A Big Discrepancy Between 3% on Savings and 5½% on Bonds

IN the face of the high interest rate being paid by the Canadian government on our recent war loan and the suggestion of a new and larger bond issue, which presumably will be no less attractive to the investor, one is constrained to question the wisdom of our Department of Finance in their attitude towards the "savings" question, which, in-so-far as our post office and government savings regulations are concerned, amounts practically to a discouragement of thrift. We refer particularly to the very low rate of interest paid on post office savings, the placing of a too low maximum on deposits and the amount of red tape with which the comparatively simple operation of depositing or withdrawing money is surrounded.

"Thriftlessness" is poor recommendation for any individual or group of individuals and we believe our Government would have been well advised years ago in placing a little higher premium on thrift by making the sacrifice a little more worth while. As it turns out, our Dominion would have reaped the further advantage of being ready for this tremendous emergency. How much easier it would have made a $300,000,000 loan if our citizens had had this amount to their credit in the Dominion savings departments. How comparatively simple a matter it would be to get their consent to transfer from (say) a 4 per cent. or 4½ per cent. savings account to a 5½ per cent. bond. The whole trouble is that the money isn't there to transfer. Our people, prosperous beyond the average, have not been encouraged in thrift.

However, the past cannot now be remedied, but we surely can profit by the experience. Isn't there an unreasonable discrepancy between the rates paid by our Government in their savings departments and the rates paid on their bonds?

* * *

Suppose it is true that a loan of $300,000,000 will be offered six months from now. Wouldn't it be a good idea to start to save it up now—today? Wouldn't that be best accomplished by the Government offering an attractive rate of interest—possibly as high as the bond itself will carry? Wouldn't it encourage thrift? Wouldn't it mean a considerable nest-egg for the inevitable demand? Wouldn't it be schooling our citizens in the habit of saving? Wouldn't it in effect go a long way towards ensuring the success of the next loan?

There is much money in Canada, but there is much being spent on extravagances. It is all very well to argue and harangue with people to save their money. The easier it comes the easier it goes—has always been so and will always be so unless you make it worth while to save. This, we believe, the Government has in its power to do if it will act promptly now.

* * *

We suggest that the Government immediately take steps to induce the working people of Canada and others to save their surplus. If 4 per cent. won't do it, pay more. $300,000,000 means less than $40 a head for us. We can do it if the incentive is sufficiently attractive. Let the government stop playing with its 3 per cent. toy and offer a real inducement to the workman, now well supplied with money, to save his surplus. Under proper conditions and given reasonable notice there is no doubt this amount can be saved. Let us start now and let our Government make the first move.

Montreal's Fair Wage Schedule

The Montreal Builders' Exchange, through Mr. D. K. Trotter, the secretary, has made a vigorous protest against an attempt now being made to give a wider application to the fair wage clause inserted in Montreal municipal contracts for buildings, construction work, etc. This wider application will affect not only the building trades, but also those industries which are more concerned with the manufacture of dressed stone, hardware, iron goods, electrical fittings, etc., and which are delivered on the various civic jobs in a finished condition. The attempt is being made to insist that in the manufacture of these articles the wages noted in the schedule shall be paid. This is, says Mr. Trotter, "an entirely new interpretation, and one which, if conceded, will have a far-reaching influence on the various industries concerned. For example, it has been urged by those who are in a position to make their demands felt, that in the yards where dressed stone is prepared for city works the city fair wage be paid. Were all the dressed stone and finished stone from a particular firm being utilized on construction work for the city, no great difficulty would be experienced in meeting this demand, but when from the same yard we learn stone is being prepared for, say, Ottawa, Toronto, and other points, and that consequently planers and stonecutters are often employed during the course of a day on stone for different jobs and in different cities, it seems clear that the enforcement of such a stipulation will hamper the organization of a firm so engaged, causing needless expense and irritation, and within certain limits restraining the trade.

"In the case of other articles (e.g., hardware and electrical fittings) which are manufactured outside Canada and which, therefore, enter into competition with the home products, another difficulty is presented. Are Canadian manufacturers and sub-contractors to have thrust upon them an artificial and purely arbitrary scale of wages (as the present one is) while their competitors are free from this unhealthy interference?" Mr. Trotter has asked for the co-operation of other bodies in defeating this attempt to extend the scope of the fair wage schedule.

Wood Blocks on Grades

We published in our December 8 issue an interesting article on the use of wood blocks for city pavements, pointing out certain advantages which this pavement possesses over other types. In this connection the following remarks from Mr. A. F. Macallum, city engineer of the city of Hamilton, Ont., are of special interest. The city of Hamilton has used wood blocks on grades up to six per cent., and, with a special construction that has been found by the city engineer to be suitable under these circumstances, very satisfactory results have been obtained. The following brief discussion by Mr. Macallum on the use of creosoted wood blocks on various grades will be read with interest by engineers throughout the Dominion.

Creosoted Wood Blocks on Grades

"When the grade of a proposed pavement exceeds three per cent. the question of a suitable pavement, and the method to be adopted in laying it, to meet the requirements of the traffic, becomes of interest. With the variability of conditions to be met with, due to our climatic changes, the limits of most paving material is soon reached, so far as the inclination of grade is concerned, unless specially manufactured.

"The writer inquired from twenty-four cities to ascertain the maximum grades upon which creosoted wood blocks had been laid, and found that one city had laid this pavement on a seven per cent. grade, one on six per cent., three on five per cent., and five on three per cent. grades. The five to seven per cent. pavements were laid under two methods, described below.

"The first method used was probably originated in this city and was used on upper James Street with the block pavement laid there in 1909 on a five and a half per cent. grade. Each block had a piece one-half an inch in width and one inch in depth cut off one face, so that while the blocks were laid at right angles to the centre line of the street, there was a space of a half inch between each row of blocks giving a good foothold for the horse-drawn traffic. These blocks were pitch-filled and the cross grade of the street was sufficient to drain out any water.

"The same method was adopted on King Street West, in this city, during the same year, and I may say that both of these pavements have been very successful in meeting the conditions of heavy traffic on two of our main streets without a cent being spent for repairs or renewals since being laid.

"The special cutting of the blocks in the manner described added considerably to the cost of the pavement and to obviate this the ordinary rectangular block was later used with creosoted laths ⅜ in. x 2 in. laid between each cross row of blocks. This was pitch-filled, as in the first method, and has been just as successful. A part of John Street South, and Bay Street, each having a grade of five and a half per cent., paved in 1911, were laid in this manner, and are today in first-class condition, and subjected to fairly heavy traffic.

"On Ravenscliffe Avenue, a purely residential street, having a six per cent. grade, blocks spaced in this manner were laid. The reason for putting such a pavement on a street like this, having very little traffic, was that the residents insisted on a creosoted wooden block pavement because of its quietness as compared with other pavements suitable for such a grade, and it has fulfilled expectations.

"From our experience we have no hesitation in recommending such a pavement on grades up to six per cent."

Canadian bank deposits continue to increase rapidly and now total $1,120,954,457. This is made up of $406,735,171 demand deposits and $714,219,286 notice deposits, both highest records for the Dominion.

Proposed Bridge Over Sauvage River

The Quebec Streams Commission, Montreal, are calling for tenders for the construction of a bridge over the Sauvage River, in connection with the dam which is being built on the St. Maurice River. The bridge is to be built at a point where the river empties into Lake St. Francis, and will replace an existing structure which will be flooded when the dam is finished. The Commission are asking for alternative bids for a wooden bridge, wooden piers, and abutments and bridge approaches; and for concrete piers and abutments and bridge approaches and steel superstructure. The wooden bridge, designed under the supervision of Mr. O. Lefebvre, the chief engineer, will be 544 feet between the abutments, and will have four spans of 136 feet each, supported by wooden crib piers and abutments filled with stone. The detail design of the steel bridge is to be submitted by the bidders, but the main feature is a bridge with three spans of 180 feet each in length, supported by two piers and two abutments of concrete, resting on solid rock. The bridge will have to support a concentrated load of 30,000 pounds. The flooring is to be of red pine. When the tenders are in the Commission will decide on the type to be constructed.

"Punch"

The British Empire, and Canada its most important unit, faces the new year with unimpaired vigor, uncountable resources, unshaken confidence and redoubled determination.

Development of Canadian Highways

The Necessity of good roads for National Progress and Production—A saving of Time and Money in Transportation.

By W. A. McLean *

THE development of roads in Canada, in essential principles, has followed the history of all other countries in this regard; and the student of the question cannot but be struck by the similarity which has existed in all countries of the world. Canada has had

(1) A period of toll roads prior to 1850;

(2) A period of railroad construction when the common road was neglected but which has resulted in the construction of 32,000 miles of steam railway with a capitalization of $2,000,000,000 including three transcontinental trunk lines;

(3) A period of bicycle influence and agitation when educational measures and some better roads organization were inaugurated; and

(4) The period of motor vehicle influence, which has finally awakened the cities to the cause of good roads as a measure of national development and prosperity—the cost to be borne not by half or quarter of the community, those residing on the farms, but by every one receiving the benefits and carrying the responsibilities of citizenship.

This is the story which might be told of the United States—with variety of detail according to local conditions. Just as there has been difference of detail between the States of Massachusetts, of Maine and of Dakota—so have local circumstances influenced the progress and results of organization in the Canadian provinces.

Provincial Organization

The Dominion (Federal) administration to the present has done nothing for roads. Primarily the control of roads is vested in the local municipality within which they lie, but every Province has a provincial highway department, from which, in varying degree, centralized influence, assistance and authority is radiated to road improvement. All this is very similar to the general situation in the United States.

Roads in nearly all countries fall naturally into a three-fold classification. There are,

(1) The main roads between towns and cities;

(2) Leading farm roads, radiating from market centres and shipping points, and

(3) Local feeders.

The natural features of any country have been very largely, a controlling factor as to which of these classes of roads has received first or chief attention.

Thus, in the Province of British Columbia, traversed by the Rocky Mountains, with rich resources of mine and forest, and fertile valleys, the construction of main roads connecting centres of population has been a feature of the provincial road programme, and upon which there has been a recent expenditure of about $15,000,000.

The prairie provinces of Saskatchewan, Alberta and Manitoba, principally agricultural, (wheat growing and ranching) with very little road material, constitute an area of earth roads, in which the grader and log-drag are to the present the principal means of improvement. Nevertheless their expenditure on roads and bridges amounts to about $2,500,000 annually.

The province of Quebec is making a special expenditure of $15,000,000 on road improvement. A portion is being granted as aid to municipal construction; but in addition a considerable mileage of main road has been built which will provide an excellent tourist route when completed next year (1916). The trunk of this main road system under the control of the Province will consist of a route from the American boundary near Plattsburgh in New York State, thence northerly to Montreal, 39 miles; a road on the north shore of the St. Lawrence easterly to Quebec city, 151 miles (in adddition to 27 miles of existing toll roads); and from Quebec city south to the American border near Jackman in Maine, 92 miles. Another "regional" road reaches from Sherbrooke to Derby Line on the American border, a distance of about 33 miles. On this system of trunk roads nearly $4,000,000 has been spent by the Province. A feature of the Quebec aid to municipal construction is that, for substantial improvement, the Government will provide the necessary capital, charging the municipality 2 per cent. for a term of 41 years, the Government meeting the balance of interest and sinking fund. About $8,000,000 has been thus appropriated to the present time.

Prince Edward Island, the small island province in the Gulf of St. Lawrence, a fertile agricultural area, is principally concerned with earth roads, all under the direction of a Provincial Department.

New Brunswick is not as yet making any large expenditure, although the beneficial influence of a provincial office is being exerted.

Nova Scotia, the most easterly province facing the Atlantic, is not in a position to make large expenditure; but the Provincial Department of Public Roads is making excellent progress with the outlay available, more especially in the improvement of earth roads, and the construction of permanent culverts and bridges. The expenditure of that department for the current year will amount to about $635,000.

Organization in Ontario

Ontario is the leading province of the Dominion, and has every variety of territory and resource. Southern Ontario is probably the most densely occupied portion of Canada where in an area of about 40,000 square miles, there is a population of about 2,500,000, one-half of which is urban. In the southern and populous portion, which is chiefly agricultural, there is a municipal expenditure on roads in the open country of over $2,000,000 annually; while the province spends about $1,500,000 annually through three road departments, viz:—

(1) Subsidies to leading market and main roads in Southern Ontario. (To this I will revert later).

(2) Trunk colonization roads in Northern Ontario.

(3) Minor colonization roads in Northern Ontario.

No part of Canada, I would point out, is so favorably placed to finance the construction of main roads as are some portions of the United States—such States

*Engineer of Highways for the Province of Ontario.—Read before Worcester Good Roads Convention.

as Massachusetts, Connecticut, or New Jersey, which are small in area and contain numerous cities which contribute to the cost of rural roads.

Unfortunately and unlike the United States, the system of municipal organization has been such that all cities are wholly separated from the county and township in which they lie, and have escaped taxation for roads in the open country. This is a situation which recent legislation has sought to correct; and provision is being made that all cities shall contribute to the cost of leading roads within a reasonable suburban area.

County Roads in Ontario

Owing to the strong claims of agricultural communities, the assistance given by the Provincial Government to the better class of construction, has been largely confined to the subsidizing of leading market roads in each county.

Ontario has both township and county organization. Township councils are elected annually, and the reeve of each township, (town and village) is, ex-officia, a member of the county council. Township councils, primarily, have control of all the roads, but a county council is authorized to take over from the townships the leading roads of the county for construction and maintenance. To this system of county roads, the Provincial Government has heretofore paid one-third of construction cost only, but under legislation of this year, will hereafter contribute 40 per cent. of the cost of construction, and 20 per cent. of the cost of maintenance. More than half of the counties are operating under this plan with good results, and to the present time, a total of over $6,000,000 has been spent on the work. It is anticipated that, under the increased subsidy, the remainder of the Province will adopt county systems in a very short time.

Counties have been somewhat lethargic in adopting the plan; but having adopted it, and having completed a reasonable mileage, the method becomes very popular. Property along the improved roads has shown decided advance in value varying with local conditions from 10 per cent. to 40 per cent.

A favorable feature of the Ontario scheme is that, by requiring counties, at the initial stage, to adopt a comprehensive plan of roads, a well connected system finally results. The work is very often, to meet local feeling, carried on in short sections, but each successive council has a permanent plan on which to work. Construction is carried on under an engineer or superintendent appointed by the county council, but all is subject to the regulation and inspection of the Provincial Department of Highways. The provincial subsidy is paid annually as the work progresses.

A county council may issue 30-year bonds to meet its own proportion of the cost, but more commonly they extend over a 20-year period. Very seldom are bonds issued for the entire expenditure of the county but as a rule to supplement a sum raised by uniform county rate. A county system will usually include about 200 miles, or 15 per cent. of the total road mileage within the county. The completion of such a system may extend over eight or ten years, so that by levying a county rate of 1.5 mills annually on the assessment during that period, only a very small municipal debt need accrue. Largely for moderate farm traffic, the county roads are of gravel or broken stone, single track, except near cities, and cost from $2,000 to $8,000 per mile, according to local conditions and traffic.

Assuming a county system constructed in ten years at a cost of $800,000 with a county assessment of $30,000,000, the annual arrangement would be as follows:—

Direct levy of 1½ mills on assessment	$ 45,000
Bond issue	3,000
Provincial subsidy, 40 per cent. of total	32,000
Total	$ 80,000

Thus in ten years (with proper maintenance additional), the county would have an asset in road improvement of $800,000 with a bond issue of only $30,000. To the latter is commonly added the cost of heavy machinery and permanent bridges, on which the provincial subsidy of 40 per cent. is also paid.

Bond issues for county roads are met on the annuity instalment plan. The sinking fund method has been almost entirely abandoned in the province for all municipal purposes, except in the larger cities. The annuity instalment plan is cheaper than the sinking fund method, safer, more easily managed, and is distinctly in favor with financiers, municipal authorities and the public.

Main Roads in Ontario

Under new legislation for main roads, more attention will be given to the development of certain trunk lines, for which there is a growing demand. The chief of these connects Ottawa on the east with Windsor (opposite Detroit) on the west, a distance of about 500 miles. A branch, 75 miles in length, would reach to the Quebec boundary (45 miles from Montreal), and another would reach from Hamilton to Niagara Falls, 45 miles. This road would form an ideal trunk highway for the southern part of the province. It would link up the various systems of county roads, would pass through the most important cities, and within twelve miles on each side is about one-half the population of the Province. Some portions of this road are now in fair condition with good gravel or broken stone surface.

The most important section, about 36 miles between Toronto and Hamilton, is now being constructed in a thoroughly substantial manner, with 4 per cent. grades, 26 feet between shoulders, and an 18-foot concrete pavement. The cost of the Toronto Hamilton section will be about $800,000 and the work is to be completed next year (1916). Other portions of the highway are now under consideration, and the linking up of the entire trunk highway is, we believe, merely a matter of reasonable growth.

The system of management provided for this class of road is somewhat unique. A main road is interpreted as one running directly between two important terminal points or cities, and therefore passing through a series of municipalities. Such series of municipalities may petition the Provincial Government for construction as a Main Road; and if the petition is endorsed by three-quarters of the municipalities affected, the Government will make surveys, prepare specifications and appoint a special board of Commissioners to take charge of the construction and maintenance of the road. The cost in the engineer's report is apportioned among the municipalities benefited, (the Government contributing 40 per cent.) and the Commissioners then act as a Court of Revision to hear the appeal of any parties affected as to the engineer's apportionment of the cost. The Commission may confirm or revise the engineer's report, and unless a majority of the municipalities then petition against the work, the Commission is authorized to proceed with construction.

Classification in Ontario

It will thus be seen that, in the Province of Ontario, the three-fold classification so desirable in road organization is being evolved in the following manner:

(1) Main trunk roads to be constructed and maintained by Special Commissions, under the guidance of the Provincial Highway Department; the cost to be met by Provincial subsidy and direct assessment on cities and rural municipalities benefited.

(2) Leading market roads, to be under the control of county councils, subject to regulations and inspection of the Provincial authorities; the cost to be met by Provincial subsidy, and county levy on all assessible property within the county, including cities.

(3) Local feeders, to be under the control of township councils, and at the expense of the township.

A Permanent Executive Staff

A difference between Canadian and American methods, with which I have frequently been impressed, is the Canadian tendency to greater permanency in tenure of office. In the American States, when a change of government takes place, a complete change of executive staff very often follows. This unfortunate political influence is no doubt recognized, and the mass of your citizens would desire to have it eliminated.

Under representative party Government, party influence cannot, and if clean and sane, need not be wholly eliminated. There is probably no important Highway Department in the world from which politics is wholly removed. But the party that does not recognize the necessity of a permanent executive force, is blind to its own best interests, as much as to the public good.

The difficulty would appear to be a failure in your organization to distinguish between "political" and "executive" responsibility; the one framing and determining a policy, the other carrying out that policy. The purely political head of a department is part of, and properly changes with each new administration. But the executive head and staff should be permanent, if reasonable efficiency is to be secured.

A permanent executive force, appointed "for life and good conduct," is the only means whereby skill, experience, and definite knowledge of local conditions can be brought into play. An experienced staff is the heart and soul of successful road system of the older countries, and should be incorporated into the highway administration of this continent as quickly as possible.

A feature of even the purely municipal road systems of Ontario, is the endeavor to create and retain permanent, and therefore, experienced men for every branch of the work. Public opinion in the United States would do well to insist on building up a permanent executive force in every branch of highway work, whether state or municipal.

What Will Good Roads Mean to the Dominion?

What Good Roads mean in point of present organization has already been outlined. What they will mean of advantage to the country might also as readily be applied to the United States.

In the Dominion of Canada there are about 250,000 miles of graded roads. Road-building is a slow process, and in most countries it has taken half a century at least to provide adequate surface construction. The immediate objective in Canada should be to substantially improve about 16 per cent. of the total, or 40,000 miles, which would carry the more concentrated market or farm traffic, while about 2 per cent. additional, or 5,000 miles should be treated in a trunk road basis. The total cost might be approximately estimated at $250,000,000 of which about $50,000,000 has been spent. The ideal of expenditure to be aimed at for this work of main road improvement (apart from small repairs and maintenance), would be about $15,000,000 annually or $2 per capita of population.

This is a substantial programme for a population of 7,500,000 people. It indicates one reason why road-building is a slow process—because it is expensive. It means that the work must be distributed over a term of years and among various administrative organizations. But so distributed, and looked at from the standpoint of annual ability, the undertaking becomes less difficult. The total twenty-year cost of maintaining a household does not worry the average man—if his annual income is sufficient for the annual outlay. Road-building is a continuous work; if properly carried on, is cumulative in its growth, and is a question of annual expenditure available to meet direct outlay, plus sinking fund, interest and cost of maintenance.

Saving in Transportation

Canada is a country of rich and varied resources. But natural resources are of value only as they are developed. A considerable part of the cost of such development is in transportation—in transferring goods from one place to another. The lessening of the cost of transportation, is a measure of economy, of national thrift, which will produce a large return in the expenditure. On this continent, the cost of team haulage is rarely less than 25 cents per ton-mile and is sometimes twice that amount. Under the favorable conditions of good roads in Europe, the cost is reduced to between 8 and 12 cents a ton-mile.

The tonnage carried over the country roads of Canada is not readily estimated; but railway statistics show that the total amount of freight carried by the railways and originating in Canada, is about 60,000,000 tons. This, for the most part, at one or both ends of the railway journey, must pass over the wagon road. And a considerable additional amount, consumed locally, passes over the wagon road without railway transportation. The average wagon haul for farm and natural produce is estimated at between seven and eight miles. It is probably a moderate assumption for Canada that a total of not less than 100,000,000 tons passes over the roads of the country with an average haul of five miles. If then the premise is true that good roads would effect a saving of ten cents per ton-mile, an adequate system of improved roads would create a profit of $50,000,000 annually on the produce and merchandise now passing over them.

The time lost in travelling over bad roads is very great. It is a fair estimate that bad roads occasion a loss of a man and team for two weeks (12 working days) annually to the average farm. With over 700,000 occupied farms in Canada, this wasted time and effort, if put into road construction, would substan-

(Continued on page 17)

Semi-rapid Transit Scheme for Toronto

Report just handed into City Council advises expenditure of eighteen million dollars — Toronto not ready for complete subway system

As a deliberate discussion of traffic conditions and requirements in the city of Toronto based on authoritative data gathered with apparently infinite care, no previous report approaches in value that just handed in to the City Council by Commissioner of Works R. C. Harris, F. A. Gaby, Chief Engineer Hydro-electric Power Commission of Ontario, and E. L. Cousins, Chief Engineer Toronto Harbor Commission. The report takes cognizance of general conditions covering a very wide range such as growth of population; location of factories; congested traffic points; vehicular traffic; Toronto Railway System; municipal car lines; Hydro Radial possibilities and many other minor factors which may influence the transportation requirements of the city of Toronto during the next quarter of a century. A rapid transit scheme, in the strict meaning of the term, is not recommended, but three trunk radial entrance lines with the necessary yards and terminal as shown in the accompanying drawing. This recommendation is based on the supposition (1) that the city of Toronto acquire the property of the Toronto Street Railway in 1921 and (2) that the waterfront viaduct will be constructed by the Grand Trunk and Canadian Pacific Railways.

The recommendations in the report are as follows:

1. The City of Toronto acquire the Toronto Railway Company at the expiration of the franchise in 1921, and thereafter operate same as a municipal railway.

2. The City should at once make a definite declaration of policy in this regard.

3. If the decision be to municipalize the service, preparatory steps should immediately be taken, in order that upon the date of franchise expiry, the City may enter into occupation and operation, without overholding tenure complications.

4. A Transportation Commission be at once appointed, consisting of representatives from the City, the Toronto Harbor Commission, and the Ontario Hydro Electric Power Commission, so constituted as to afford the City majority representation. This Commission should be vested with all necessary power to plan, control and direct all transportation and terminal facilities of every kind whatsoever, (exclusive of existing steam railways), including present or projected municipal lines within the corporate limits of the municipality, and to prepare and arrange for the acquisition and operation of the Toronto Railway Company as a municipal utility, upon expiry of the franchise rights of said Company; the powers of this Commission to be sufficiently inclusive to embrace all railway transportation facilities as aforesaid, and to be implemented from time to time in order to accomplish the full intent of this recommendation. The Harbor Board and the Ontario Hydro Electric Power Commission, should be represented upon this Commission in extension of the policy of Council already expressed in the appointment of the Board charged with the duty of making this report, and for the same reasons which guided that body in the constitution of such Board, viz.: That the future transportation facilities within Toronto should be co-ordinated with regard to the services, rights and holdings of the bodies aforementioned, with particular reference to radial entrance and railways, the operations of the Harbor Commission as Trustees for the City, and local street railway service within the City Limits. The Ontario Hydro Electric Power Commission, through their Municipal Radial Railway project, is at present undertaking the construction and development of some 1,000 miles of radial railways, with Toronto as a main terminal focal point; the Harbor Commission as Trustees for the City, control the proposed east and west trunk radial railway entrances, together with the proposed terminal site, contemplated team track delivery yards and general sorting yard, while the City has jurisdiction over all public streets, embracing surface, elevated and underground rights. Even cursory consideration, will demonstrate the necessity of harmonizing all these interests, if transportation problems are to receive adequate and effective treatment. This can best be accomplished by the creation of a Commission constituted as recommended

5. The construction of the three radial entrance lines, with necessary yards and terminal, as shown on Drawing No. 18 be proceeded with when conditions warrant and finance permits.

6. A rapid transit system in the strict meaning of the term be not adopted.

7. The radial railway trunk line entrances be used for a semi-rapid transit service, as conditions warrant, to serve the population in the districts lying at present without and adjacent to the existing City Limits.

8. It may be necessary to procure legislation amending existing Acts, in order to give effect to the foregoing.

9. The use of any of the lines, yards, terminals and anything whatsoever, in any way relating or appertaining thereto, by any other railway than those of the Hydro Electric Railway Union and the City, shall not at any time be permitted, until such railway shall have obtained the consent of the Hydro Electric Power Commission thereto.

10. We do not make suggestion as to finance and reimbursement, feeling that this does not lie within our jurisdiction, but is for each to take up with his respective principles.

These recommendations are based on certain conclusions drawn by the members of this Advisory Committee as a result of their researches and deliberations. These conclusions, in part, are to the effect that there is no congestion on Toronto's streets that cannot be relieved by a proper utilization of existing surface lines; that an up-town terminal is not feasible; that ample provision must be made for future expansion and for co-ordination of rail and water transportation; also that the present gauge on the Toronto Street Railway tracks must, for a proper traffic unification, be reduced to standard. The following are the conclusions in full:

Conclusions

After detailed consideration of the various factors, entering into and affecting the problem as hereinbefore recited, we have concluded that:

1. Additional civic car lines laid between now and 1921, without the limits of 1891, but within the limits of 1915, will, after acquisition by the City, of the Toronto Railway Company in 1921, adequately serve all sections within the present City limits: the maximum time necessary to reach extreme destination being thirty-five minutes.

2. The existing surface system of the Toronto Railway Company, if provided with improved equipment and operated at higher service efficiency can be made to adequately serve the City within the limits of 1891.

3. As traffic officers become more efficient in direction and citizens better appreciate the functions of such officials, the movement of rail, vehicular and pedestrian traffic will be

greatly facilitated, with consequent saving of time and added safety to all.

4. If a sufficient number of cars of modern type were provided, thereby minimizing overcrowding and the public educated to embark and debark with reasonable speed, it would result in more rapid operation of the railway system, and the facilitation of other classes of traffic.

5. There is comparatively little congestion in Toronto streets. This may be further minimized by regulation of standing vehicles on, and diversion of slow-moving, heavily laden traffic from, main heavily-trafficked thoroughfares in the central area.

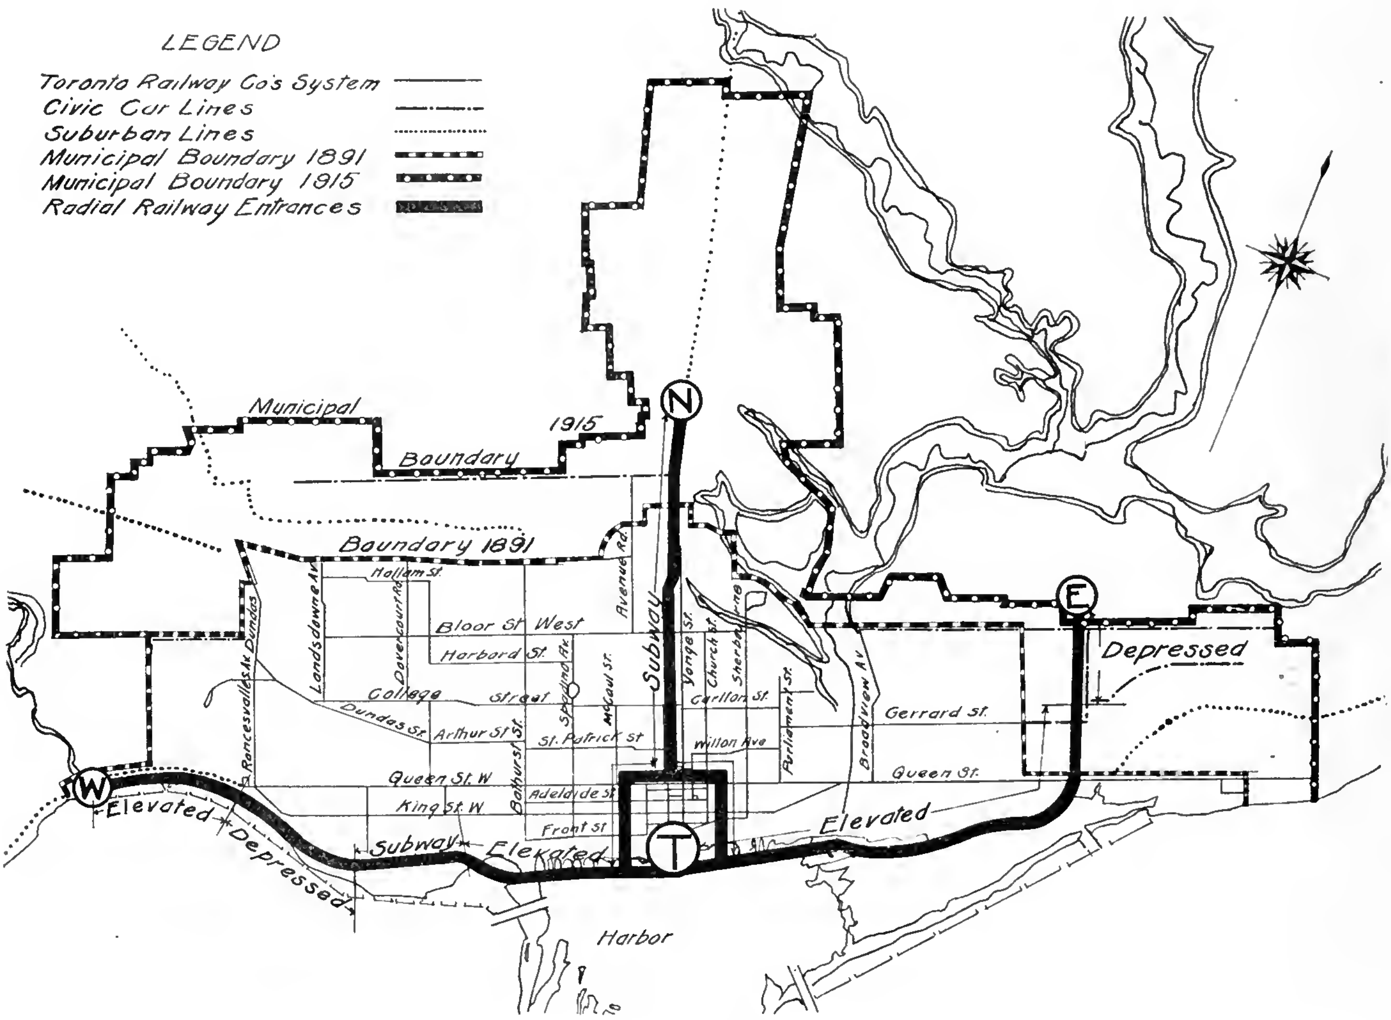
Radial Railway Entrance

1. That the following railways entering the outlying portions of Toronto, viz:—

(a) The Toronto & York Radial Railway embracing the Metropolitan, running north on Yonge Street; the Kingston Road line from the Woodbine; the Port Credit line from Sunnyside; (b) The Toronto Suburban to Lambton, Weston and Woodbridge, from Keele and Dundas Streets, cannot be considered rapid transit interurban lines, as in all cases they operate mainly on the highway, at low speeds. The people of Toronto and the Province have not had the advantages of modern rapid interurban service, such as is operated in many parts of the United States. When the Hydro Radial project becomes an accomplished fact, the system of which the section operating between London and Port Stanley is a happy augury, the entire population of the Province will derive therefrom, tangible benefits, which result to a community from a modern, high speed, properly equipped and efficiently operated system.

2. That the most feasible entrances from the east and west lie along the waterfront route. The entrance from the north may be readily effected by subway construction. The foregoing conclusions were arrived at after careful reconnaissance of the possible routes of entrance for radial railways, in the City and its environs, and detailed survey of one hundred and fifty miles of line.

3. From the viewpoint of economy of operation and utility, it is essential that the terminal be located on the axis of maximum movement. Having regard for the past suggestions for an up-town terminal, we thoroughly investigated this possibility, with the result, that aside from operating considerations, the additional cost of $8,000,000 embracing a four track subway from the waterfront to College Street, and the erection of a terminal at the latter point, proved it unfeasible.



Drawing No. 18.

The foregoing indicates the necessity for location on waterfront route.

The same consideration applies also to the location of yards on the waterfront property, in view of its natural advantages.

4. It is prudent to make present provision for future expansion covering trackage for trunk line entrances and terminal facilities, therefore the necessary sites should now be provided for ultimate development.

5. That it is necessary to make ample provision for the co-ordination of rail and water transportation and the proper interchange of all traffic.

6. The radial railway trunk lines should. as the future

(Continued on page 12)

The Quantity System of Estimating

A plea for a more economical system of figuring the Cost of Buildings—Make plans and specifications definite

By G. Alexander Wright

The ever-increasing amount of unproductive time, and usually money, which contractors are called upon to expend in preparing, gratuitously, quantities, as well as prices, often for an owner's benefit, suggests that the time has arrived when all concerned should take up, and seriously consider, the possibility of adopting a modern and more sensible system of estimating, such, for example, as has been long in successful operation in older communities. Not a mere copying of such methods, for I advocate the creation of a standardized method of our own—an American system, practical above all things; a system that will be in line with our otherwise progressive building methods; a system that shall be clear and accurate, and that shall stand for square dealing between contractor and owner—in short, a system that shall give every man his due, no more and no less; a progressive system, free from the defects of other systems, such as unnecessary elaboration, and yet one that will reveal to the bidder, at a glance, the actual quantity of material and labor in a structure, in any individual trade. When bidders are invited to submit bids, they are theoretically asked, of course, to submit competitive prices, but in actual practice their bids are based upon competitive quantities, before the competition in prices commences; which, in my opinion, is as unjust to the contractor as it is ridiculous. A building can only contain a certain amount of material, and no amount of figuring by contractors against each other can make that quantity any more or any less. Where, then, is the sense in a dozen or more general contractors competing against each other in taking quantities? One or more bidders, through being hurried, or being unable to take off the quantities accurately, leaves something out. What happens? Their bids are consequently low, and the owner benefits, at the low bidder's expense, whilst the competent or more careful bidder loses the job, because his quantities are more accurate, or because there may have been room for uncertainty when figuring the plans and specifications.

Antiquated Estimating Practices

Not long ago, a general contractor (whom I have known over twenty years) told me that if contractors figured to do competitive work just exactly as plans and specifications called for, a man would not get "one job in fifty." Now, if this is true, and personally I believe it is, there is something very rotten in our methods. In my judgment it lies in our antiquated estimating practices.

Those of us who know something of the unsatisfactory conditions under which bidders are often obliged to figure, time after time without result, have realized that hundreds of thousands of dollars in time and money are taken from contractors' pockets every year, simply because they do not, so far, limit competition between themselves to the matter of prices. They go on competing, and I suggest gambling, with each other as to the quantity of material a building will take, whereas I contend that that is a question of fact, and that competition in the quantities between contractors never can, and never will, in any way, change the fact that a certain fixed quantity of material and labor is necessary to do every job. There can be no legitimate competition in taking off quantities of materials, except that unfortunate competition which bidders make themselves when they take off too much, or, as too often happens, too little.

The legitimate competition can only come in where one man can handle a job better than another, or one man may have some advantage over another in buying, and so forth. All this kind of competition is legitimate enough, but it must be obvious that no amount of figuring can reduce the real quantity of material which a building will take, and so my contention is that it would be proper and fair to start all bidders figuring upon the same basis, by furnishing each with a schedule, or bill of quantities, showing accurately and clearly the different quantities and kinds of materials which the bidder is invited to figure upon; and even then there would be plenty of competition left, in placing profitable prices against each item.

Present Method Wasteful

Our present method (or rather, want of method) in estimating, and the rapid strides being made in construction, are, as I have said, forcing upon the contractor, more and more every year, an increasing waste of time and money in figuring out quantities. This senseless waste and competition cannot go on for ever. It has already brought men to bankruptcy all over the country, and has often prevented the making of a proper and legitimate profit among those who do succeed in keeping their heads above water.

This is a live question, and it deserves the earnest consideration of all contractors' associations and architectural societies from the Atlantic to the Pacific Coast.

No new or untried principle is involved. It is simply that of a definite quantity of work, for a definite amount of money. In substance the owner says, "I want this quantity of work done. The drawings and specifications show you how this quantity of work is to be assembled or put together. Now, tell me how much money will this cost? I want you to do the quantity of work called for; no more, no less."

At present, the successful bidder often says, in effect, to an owner, "I will erect your building according to plans and specifications," but—mentally—he says, "I do not figure that it will take as much flooring, concrete, plastering or painting as my competitors think it will!" Let me ask, Is this a proper or fair competition between contractors themselves? Is it fair to their own interests? There is only one individual who stands to gain anything under such imperfect methods, the owner, and not always he.

It may be stated that the Quantity System is equally applicable to engineering works, such as railroad work, sewerage disposal schemes, canals, pumping stations, etc.

Before proceeding to a further consideration of this subject, I may be pardoned perhaps for expressing the opinion, after having had over twenty years' intimate experience with the workings of the Quantity System of estimating, and over another twenty years in San Francisco (without any such system), that I know of nothing in connection with the work of the contractor that would be more beneficial than the adoption of some equitable recognized system of estimating upon bills of quantities, and these latter would be equally valuable, whether sub-contracts were eventually let or not.

It is not the idea that we accept the methods of any particular country—the author hopes he is too much of an American citizen to suggest that—but where contractors in older communities favor a certain system to the exclusion of the very thing we practise here, then I suggest that we might well stop for a moment and take notice of what is being done. For example, in the year 1909 a conference was held in Great Britain between the National Federation of Building Trade Employers, the Institute of Builders and the London Master Builders' Association, and a resolution was adopted recommending contractors who were members of these powerful organizations to decline to bid in competition against each other, unless bills of quantities were supplied for their use at the owner's expense. A deputation from these contractors' organizations afterwards attended before the principal body of architects, who promised to further the aims of the contractors as far as was within their power; and to-day the Quantity System is in full operation, not only in the case of private owners, but in all building work for government and municipal authorities, and upon the principle that it is impossible to obtain accurate bids without accurate quantities.

There must be some good reason for all this, and I suggest that it is worth consideration by any body of men, architects or contractors, who are endeavoring to get and to do better work, and thus elevate the building business to the honorable position which it is entitled to occupy, and to bring about such conditions as will cause owners to hold the competent architect, as well as the contractor, in higher esteem, and not regard him, as is too often the case now, with suspicion.

Existing Conditions

Now let us consider, for a moment, a few of the disadvantages of existing methods:

First—The time usually given for figuring is far too short for the accurate taking off of quantities, in addition to the pricing and figuring out of the many items. A bidder usually has contract work in progress, and other matters to be attended to during the daytime; other plans are to be figured by a certain time, and but little can be accomplished in the eight-hour working day, and so advantage must be taken of the night hours, sometimes all night, and even Sundays (as I happen to know), and any other time. Only those who have worked under these conditions and over blue prints at night, hour after hour, taking off items, can appreciate the many difficulties, pitfalls, and liability to error through figuring against time, after the real work of the business day is over. But the plans must be returned first thing in the morning, or the bid must be in by a certain hour the next day. Nothing but hurry—hurry—hurry. In not a few cases more information is necessary; something is not quite clear. The plans and specifications do not agree on some point. Which is right? There is no time to find out, the only person who can enlighten you is asleep, perhaps, while the careful estimator is burning the midnight oil, and wrestling with problems which can be avoided and entirely eliminated under a more modern system of estimating.

Again, the careful bidder who honestly tries to get in all the items, and figures to do the work as called for, is frequently beaten by a less competent bidder, who forgets something, or who, maybe, is willing to take a chance anyway, in order to get the job. True, omissions in lists of materials are sometimes unavoidable, under existing methods, which unfortunately aim at speed rather than accuracy.

It is, to say the least, disappointing to a careful bidder on a large job to find his bid just above the lowest, and after the low man has signed up the contract, it develops that the painting, or some such item, was left out. This, however, could not occur with the Quantity System.

This is no overdrawn picture, as I know from personal experience. The competent bidder who gets in all his items to-day is usually under a disadvantage, unless he happens to be figuring against men of his own stamp. Meanwhile, it would appear that the chances are in favor of the owner, most of the time, and it seems to be a case of "heads I win, tails you lose." Surely it is time there was a change.

The existence of present conditions, whilst much to be regretted, is due to a blind continuance of early-day custom. It is in no way up to date, nor conducive to progress, nor to that business success to which a bona fide contractor is entitled. It is entirely unsuited to modern construction and modern methods. The tallow candle, years ago, was a great invention, but how many of us would light our homes to-day by this method? And yet our estimating methods of to-day date from the same identical period as the tallow candle. Other countries have long ago graduated from such primitive methods, but we are content to stand still, and we are, in this respect, away behind the times. It seems to be almost inconceivable that shrewd business men are still willing to spend their time, all going over the same ground, figuring against each other on quantities, knowing all the time that they are all, save one (and sometimes even that one), simply wasting their time. By the adoption of some sensible system, all this quantity taking could be done by one competent person.

The great difference we find in bids arises, in my opinion, not so much in the prices or money values placed against the quantities, as it does from errors in the quantities themselves, the accurate preparation of which calls for special training and continuous concentration of mind, which the busy contractor of to-day can seldom find time to acquire.

Now we will investigate a bill of quantities, such as we are considering. What is it? and how is it used?

First of all, it is a document, handed free of expense to each bidder, lithographed or similarly duplicated, in order that all bidders' copies may be exactly alike. It will contain everything which it is essential for a contractor to know when making up a figure, with a separate section for each trade, such as excavation, concrete, brickwork, and so forth. A general summary is provided at the end of the bill, in which is entered the net cost of each trade; this summary is footed up, the profit the bidder expects to make is added, plus the cost of the quantities, the result being, of course, the amount of the bid.

The methods of measurement must conform to the standards used by each individual trade, and through the bill the greatest care is taken to have everything systematized; all cubic, square and lineal feet, and numbers of items, will be found all together under their respective heads. In this way, immediate reference may be made to any item required, even though the entire bill may contain hundreds of items, and so every item has its proper place—nothing is left to chance. Detail sketches also appear in the margins whenever necessary, to show a bidder at a glance what is required. These, as we know, are of more value to an estimator than the long written descriptions one sometimes finds in specifications. The keynote of the Quantity Surveyor is accuracy. In going through the drawings and specifications he has come across all those doubtful questions which always crop up when figuring under present methods. He will have taken them all up with the architect, and adjusted them, before the quantities are handed to bidders, so that everything is all plain sailing.

Keynote—Accuracy

Nothing is "near enough" for a Quantity Surveyor—he scrutinizes every part of the work closely, clears up any doubts, or anything capable of a double interpretation, and his work leaves no loopholes for either the owner, the contractor or the architect to take advantage of. The result is that it is seldom necessary for a bidder to ask questions of the architect when making up a figure. If he should wish to do so probably he would be referred to the surveyor, who is familiar with every minute detail of the work.

Further, and right here, lies one of the greatest advantages of the Quantity System. It is not necessary, except in a general way, for a bidder to study the drawings and specifications at all, and he certainly does not have to figure them. He simply prices the bill of quantities, and, in these days of hurry and bustle, this is as much as a contractor can be expected to do for nothing. This enables the competent contractor (the one who has unit prices at his finger ends) to make up a bid for, say a $100,000 building, in a few hours, and he has the satisfaction of knowing, when the unit price is placed against each item, that nothing has been forgotten; in other words, he only contracts to furnish so much material and labor—and surely this is absolutely right in principle. Good reasons exist why the general contractor should have faith in his own judgment and accustom himself to price items in every trade which goes to make up the building business. It is the only consistent method of estimating, for anyone who claims to be a general contractor. Experience has taught most competent men that it pays to do it. The mere getting together of figures from sub-bidders, and footing up the totals of the lowest, is not estimating at all. That is mere schoolboy work. However, I am led to believe that this is now the exception among general contractors in San Francisco rather than the rule. The ideal contractor is the one who makes up his own estimates, and not he who is dependent, for any reason, upon sub-contractors, who thus become the real estimators. If every general contractor would keep a prime-cost book of all trades, and quantities were supplied to him, he would soon be in a position to give a fairly close figure upon any sized structure, without first taking sub-bids, and this I suggest is the most consistent, satisfactory, and profitable method to pursue, when bidding upon work as a whole; but of course it requires care and experience.

Further, one of the greatest arguments in favor of letting contracts as a whole is, of course, the fact that a general contractor has the ability to figure all trades in his own office, and that he knows how to, and will supervise the work of sub-contractors, if any. If architects can be assured of this being done, it would be better for all concerned.

In general practice I believe the accuracy of the bill of quantities should be guaranteed. Such a document might well be made the basis of the contract, equally with the drawings and specifications; if this were done, the chief cause of disputes between owner and contractor would be removed.

This, I submit, is entirely logical and right—a certain quantity of work for a certain sum of money, the owner to determine the former and the contractor to fix the latter. Surely this is morally just and fair.

Educating the Surveyor

It may be asked, Where are these competent surveyors to be found? And it would be a natural inquiry, as it is no part of the duty of architects to prepare such quantities. In fact, the relation of the architect to the contractor should preclude him from having anything to do with furnishing quantities. This should be attended to by a disinterested specialist—the quantity surveyor. In older countries, young men of education are now apprenticed to practising surveyors, and it has become a recognized profession. Years ago these quantity surveyors frequently came from the ranks of the architects; others possessing the necessary education were possibly contractors, building superintendents or estimators. I have known contractors' representatives who commenced life in the workshop, who, after securing the advantages of special training, made experienced and very competent quantity surveyors. There must be a beginning to everything, and doubtless there are many men in this country who, after some little training in the technique of this work, should make reliable quantity surveyors. The principal qualifications are honesty of purpose and a knowledge of architecture and construction. The surveyor should be a neat draughtsman and have actual experience in conducting building operations. He should possess the ability to readily detect discrepancies or conditions which might give rise to misunderstanding during construction, and last, but not least, the necessary mentality to act disinterestedly He must do what is right in measuring, as between the contractor and the owner. The usual custom is for the architect to furnish the quantity surveyor with a set of the drawings and a draft specification, and the latter then commences work in his own offices. During this period the architect and surveyor are in frequent consultation, to the end that all uncertainties are cleared up and adjusted upon the drawings and specifications. In short, no effort is spared to obtain clearness and accuracy before bidders commence figuring.

Such uncertainties are bound to crop up; they are unavoidable. They nevertheless perplex the contractor when he is figuring, and his foreman on the job, and create unnecessary trouble and sometimes bitter disputes; and then, in such cases, one of the parties to the contract is usually a loser.

Bill of Quantities

Now that we have briefly considered the qualifications of a quantity surveyor, let us take note of what the preparation of a bill of quantities involves. It may well be said that during the last forty years it has been brought to a mathematical science, and yet it is really surprising what a vague idea exists concerning the methods, objects and uses of the Quantity System. The fact remains, however, that where the system has been adopted, responsible contractors refuse to figure without it. Some day that will be the attitude of contractors in this country—when they fully realize the folly of wasting their time and money in competing against each other on quantities as well as on prices.

But to return: Three distinct processes are involved, and each process calls for different operations.

First—"Taking off" and entering every item (or "dimension," as it is called) upon the dimension sheets. This is always done in exactly the same order, in every building; no dimension, however small, is omitted—no guess-work of any kind is permitted. The exact location in the building of every dimension taken is carefully noted, and every figure or note taken is carefully preserved for future reference.

It is impossible to illustrate here the work in detail involved in taking off each trade, but the following may serve to show the general idea: Let us follow a surveyor for a moment in taking off his dimensions for a few items of—we will say common brick work. He always commences taking dimensions at the same point on each floor plan; every length of wall from one angle to the next is measured separately and the dimensions entered in "waste," as it is termed. We will assume that it takes, say, fourteen dimensions, and their locations are permanently recorded, footed up, and the total lineal feet is then placed immediately below this, and a line drawn across the column to separate it from the next item. The dimension is squared, i. e., the number of square feet these figures represent is figured out, and opposite to the total we find a description, thus, for example: 21-inch wall of standard common brick work laid up with lime, mortar and Portland cement, gauged three to one, pointed with flat joints one side for whitewash and raked out the other side for cementing.

In good practice it might be best to give the number of square feet superficial of wall, and give the thickness. The same method is adopted with each storey, with its varying thicknesses of walls, every dimension being entered in precisely the same order, with its particular location noted.

Then we come to deduction of openings. Those with inside and outside reveals (as in the case of box-frame windows) are taken separately, door openings the same. Those of one size and one thickness of wall are "timesed," as we say, and entered in the dimension column, so; "Ddt. 9/3 feet 9 inches x 7 feet 13 inch outside wall, fifth floor."

Then should follow an item, "extra labor," to so many 8-inch common brick segment arches in, say, three half-brick row-locks to 4-foot 6-inch openings with 3-inch rise in 8-inch wall, include for cutting skewbacks, etc., and for woodturning piece and setting and striking. In case richer mortar was specified for arches, it would be so stated, and the proportions.

When rough cutting to brick work is required, every square foot of it would be measured. Brick work in footings or foundations, or walls below ground or at unusual heights, should be all segregated and given separately, with full descriptions.

Such items as the following are then taken by the square yard or square foot—viz., selected common brick facing. If joints are struck and cut (as face work), it is taken as a separate item, as should be the case with any portions that are to be pointed with special or colored mortar. Cementing by the square yard if on ordinary plain surfaces, but if in widths of 12 inches or under, then this is separated and taken by lineal foot; should this work occur on circular surfaces, it would be so described, kept separate, and the radius given. Lineal dimensions are taken of all rough splays and chamfers, flues, pointing to flashings, projecting courses, with the number of mitres, splays, or stops in same; brick sills, with the returns, are numbered, if any. The labor of forming quoins, square or splayed, and (in certain cases) the lineal feet of plumbing angles and reveals, might be taken, also leveling up for joists, bond iron and the like.

The foregoing applies to common brick work, as before stated. Now, where "face" brick are used, the entire surface of such facing is measured by the square foot, including reveals and soffits (but openings deducted), the kind of mortar and the labor of pointing being given. Here would be taken such items as face arches. Fair cutting by the square foot on same principle as mentioned for common brick work. Then come lineal feet of each course, of which figured sketches should appear. Raking mouldings or belts separate; then follow the number of external, internal, raking, skew or other mitres; also square ends, etc. (if any). All other lineal feet items follow in their proper order, and then in a similar way, concluding with numbered items, which would be described and (if necessary) sketched in the margin. I am aware that this is but a very elementary illustration of the detailed method of taking off, but the principle applies throughout every department, in every trade, from the excavator to the painter, but it would be too great an undertaking to go fully into details here in each case.

Surveyors' quantities are usually measured net, and it is so stated in the preamble of the bill—upon the understanding that the unit price for each item is to be made, by the contractor, to cover trade customs, etc., which differ in each locality.

The before-mentioned dimension sheets are usually checked over with the drawings by a second person, and then all totals are abstracted; that is to say, they are transferred to abstract sheets, under separate headings. In this way many similar items of the same value are collected together and footed up and checked. This reduces the number of items which appear eventually in the finished bill, which is written direct from those abstract sheets, and any further sketches or descriptions necessary for the bidder to thoroughly understand what is required are then finally added. When completed, a sufficient number of copies of these bills are lithographed, or otherwise duplicated, and a copy is sent by the surveyor to the list of prospective bidders, whose names and addresses have been previously furnished him by the architect.

Advantages of Quantity System

Some of the advantages of the Quantity System of estimating to the contractor are as follows:

1. Saving of time and money.
2. Greater precision in measuring.
3. No uncertainty as to interpretation of plans or specifications (the quantities should govern).
4. No visits to the architect's office when figuring, for explanations or otherwise.
5. No other work is contracted for except the quantity set forth in the quantities.
6. The contractor, if he so desires, can check up the quantities before signing the contract. In an American system of estimating, the quantities should, I think, form part of the contract.
7. No bidder can inadvertently leave out anything, and so in this way arrive at too low a figure.
8. Not having to spend time taking out his quantities, the contractor has time to attend to more profitable business.
9. Systematically arranged bills of quantities duly priced (whether work has been secured or not) form excellent data for making future estimates.

Semi-rapid Transit Scheme for Toronto

(Concluded)

demands, and the City extends, provide for the operation of semi-rapid transit lines to serve outlying districts.

Rapid Transit Lines

1. The streets in the central area are sufficient to care for future traction and vehicular demands, provided reasonable regulations are enacted, and enforced, governing vehicular and pedestrian traffic.

2. Traffic may be much facilitated by an increase in speed of the existing Toronto Railway units. This entails improved equipment, track, routing and operation, together with the adoption of up-to-date loading and unloading facilities, and the much needed education of the public to embark and debark speedily. The accomplishment of this, together with adequate extension of surface lines, will make it possible to travel from the centre of the present city limits within a thirty-five minute period.

We have been assisted to the foregoing conclusions by the study of Drawings, Nos. 8 to 15 inclusive, showing present volume of traffic with origin and destination, lines of heaviest movement, and street traffic counts.

3. In relation to the matter of change of gauge, notwithstanding that almost every economic consideration declares against it, the dominant factor is that of future traffic unification, between radial, semi-rapid, and city surface lines, and this is impossible without the reduction of the present gauge from four feet ten and seven eighths to four feet eight and one-half inches.

4. As hereinbefore indicated, there is no justification whatever for the construction, in the City of Toronto, of a rapid transit system in the strict sense of the term.

The Confederation Construction Company, contractors on Section 3, Welland Ship Canal, have placed an order with M. Beatty & Sons, Limited, Welland, Ont., for six electric hoists. Two of these are 50 h.p. with single drums, two 50 h.p. with double drums, and two 35 h.p. with double drums. All are to be used on the new concrete handling plant which the construction company are building this winter for use on the Twin Flight Locks next spring.

The Toronto-to-Hamilton Highway

Forty-mile concrete roadway well advanced—Advantages seen in increased land values and heavier and more frequent traffic

Now that the construction work of the Toronto-Hamilton Highway Commission is closed down for the present season a brief description of what has been accomplished during the past summer will be interesting. The total distance is approximately forty miles, as shown in the map herewith. Of this total distance approximately seventeen is completed, and the grading is done on most of the remaining twenty-three miles. Some delay has been caused near both the Toronto and Hamilton terminals on account of the difficulty of coming to an agreement with the municipalities concerned on the best location of the roadway. It will be remembered that this work was undertaken very largely to relieve the labor situation which existed at the time the project was first outlined, and naturally the plans were not as complete and definitely outlined as would otherwise have been the case. There is still to be determined the gradient at which the road will

Fig. 1.—Expansion joints are placed every 35 ft.

enter the city of Hamilton; also the exact location through the municipalities lying immediately west of Toronto. If these matters can be decided upon in time for spring work it is stated that there should be nothing to prevent the completion of this highway in a few weeks—say, three months at the latest.

Considering that a very large amount of extra work had to be done that was not covered in the original estimates, splendid progress has been made with the roadway to date. As an example of this extra work it may be mentioned that the culverts along the way, which were at first reported to be in a fair state of repair, were later found to be unsatisfactory, and had to be replaced by permanent structures. A considerable amount of extra work has also been done in the towns and villages through which the roadway passes, as, for example, in Oakville, where the roadway is widened from eighteen to fifty feet along the main street. The same is true to a smaller extent in other municipalities through which the roadway leads.

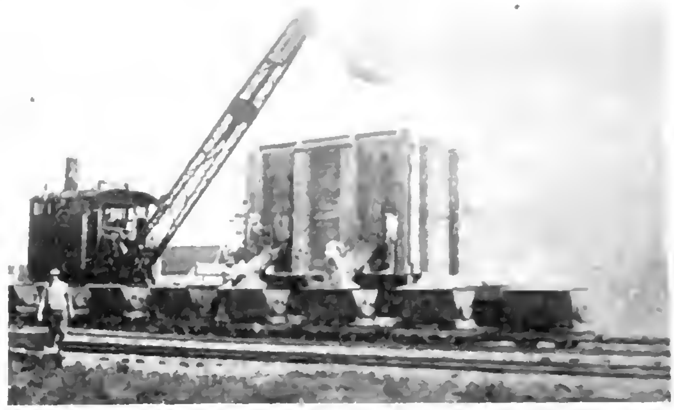


Fig. 2.—Time was saved in handling material.

That this work has been prosecuted with considerable vigor is indicated by the fact that six mixing gangs were employed, one of which on a certain occasion made a record of 630 lineal feet of 18-ft. roadway in a twelve-hour day. The average ran about 420 feet a day of ten hours for each gang; so that the six gangs could be depended upon to do a mile about every two days under favorable working conditions.

A section drawing of the roadway is shown in Fig. 3 herewith. The road is first graded 26 ft. wide, perfectly level, with a ditch on each side, the depth of the ditch depending, of course, on the road grade. The concrete roadway in general is 18 ft. wide, leaving a 4 ft. strip at each side between the concrete and the ditch. This strip is, for the most part, filled in with such earth as happens to be most easily available. It was the original intention to macadamize these strips, but the extra cost did not appear to be offset by sufficient added advantages. This earth-fill does not in general extend to the very edge, a narrow berm of some six inches being left to prevent the earth from falling into the ditch. The concrete material is six inches deep at the edges, grading up uniformly to $8\frac{1}{4}$ inches depth at the centre of the roadway. Composition of concrete is $1:1\frac{1}{2}:3$.

The photograph herewith illustrates a number of interesting phases of the construction operations. The mixers used were the Austin Cube machines, half yard capacity, one of which is shown in Fig. 7. This mach-

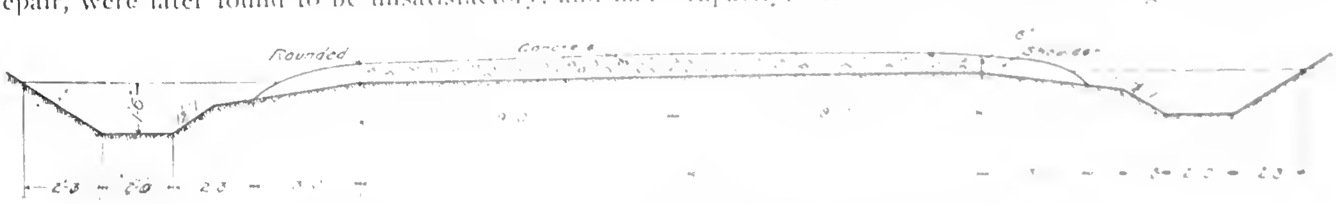

Fig. 3.—Section of Toronto-Hamilton concrete roadway—26 ft. overall, width of concrete 18 ft.

Fig. 4.—Divided float in use at expansion joint.

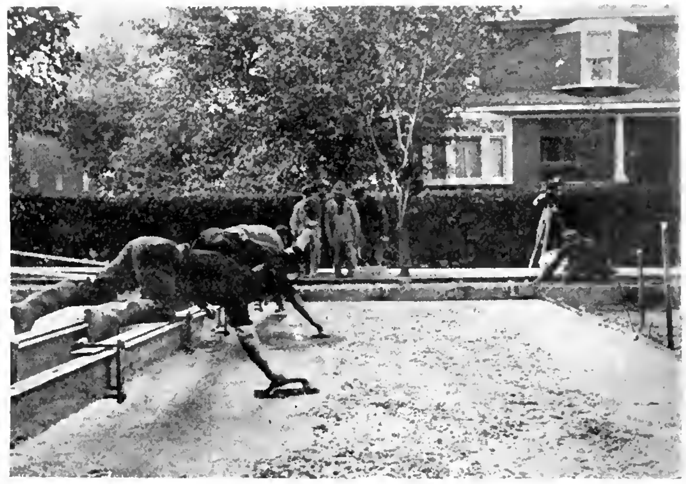

Fig. 5.—Bridge from which men complete the "floating."

ine is supplied with a 20-ft. trackway, along which the bucket carrying the concrete mix runs, and which can be operated through a wide angle. This arrangement allows of a very even distribution of the concrete over the roadway. Fig. 7 shows the men levelling the concrete, after which the proper grade is given to it with a template or strikeboard, also shown. Fig. 4 shows the condition in which the roadway is left by this strikeboard. It is later smoothed over by hand-floats, as shown in the same figure.

Fig. 4 also shows one of the expansion joints. These joints are placed every 35 feet. A better view is shown in Fig. 1. The expansion joints are approximately ¼ in. thick. When the roadway is completed they are trimmed off evenly with the surface with a sharp spade or other suitable tool.

Fig. 4 also shows a quantity of newly poured concrete roadway covered with tarpaulin to prevent drying out during the early stages of the setting process. The practice followed throughout was to cover with tarpaulin as soon as completed and leave for a few hours. The tarpaulin was then removed and replaced by about two inches of earth, which was kept damp during the first ten days and finally removed after twenty-one days, when the roadway was opened for public traffic.

One of the difficulties in placing the concrete in successive sections in a roadway of this sort is in preserving a uniform level on both sides of the expansion joint. On the Toronto-Hamilton highway this is accomplished by the use of a divided tamp, which is followed up by a divided float. One of these tamps is shown lying on the ground on the lower left-hand corner of Fig. 1, and the divided float is shown in operation in Fig. 4. In this way a perfectly even surface is obtained, so that there is no jolt to a vehicle passing from one section to another.

Another interesting feature of this work is the travelling platform on which the "floaters" work, no workmen being allowed to place a foot on the roadway after the floating operation has been completed. This platform or bridge is shown in operation in Fig. 5, which is a view of the 50-ft. roadway being placed along the main street of Oakville. The bridge moves along on rollers placed at each end just outside the curb.

Fig. 2 is an interesting view indicating how time was saved in handling material. The box-like structure is mounted on a flat car, and kept filled with crushed stone, either from a stock supply as shown in the figure, or direct from railway cars as brought in. It will be seen that the dump-cars are being filled two at a time from two chutes which supply material from

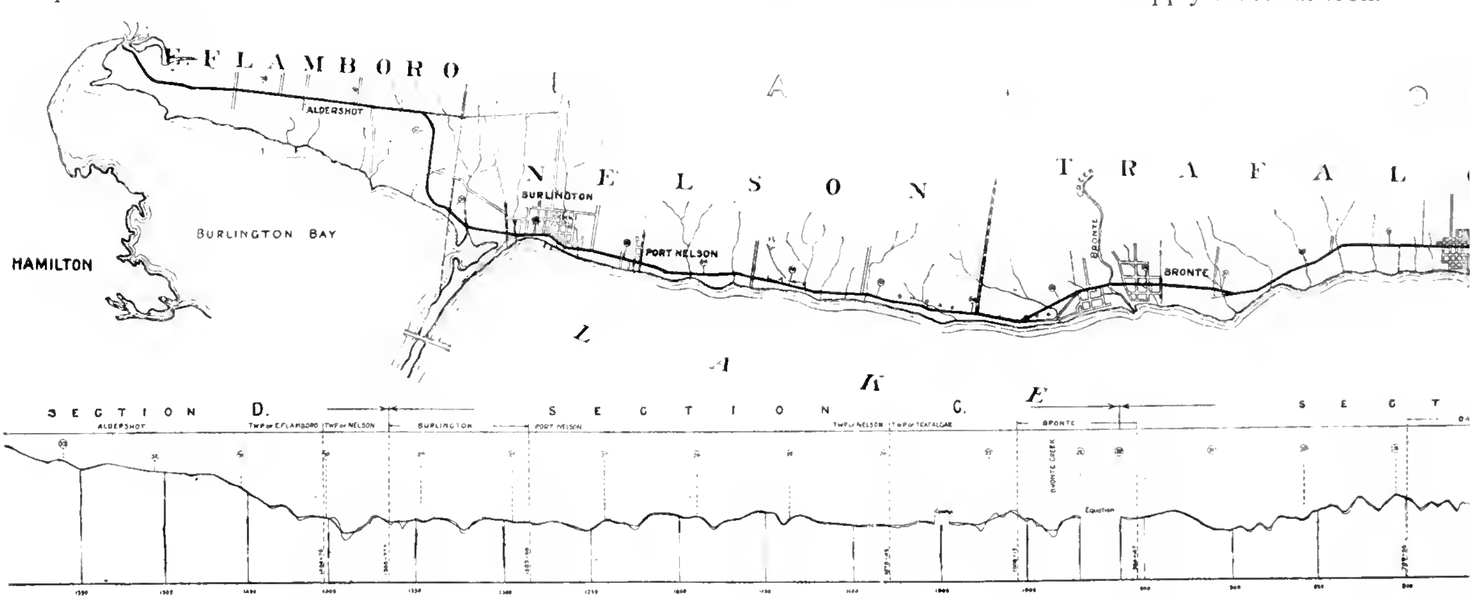

Fig. 6.—Plan of concrete roadway which will connect Toronto and Hamilton through one of the most attractive scenic districts in the prov

Fig. 7.—Mixing and distributing machine.

Fig 8.—Scarifier operated by Traction Engine.

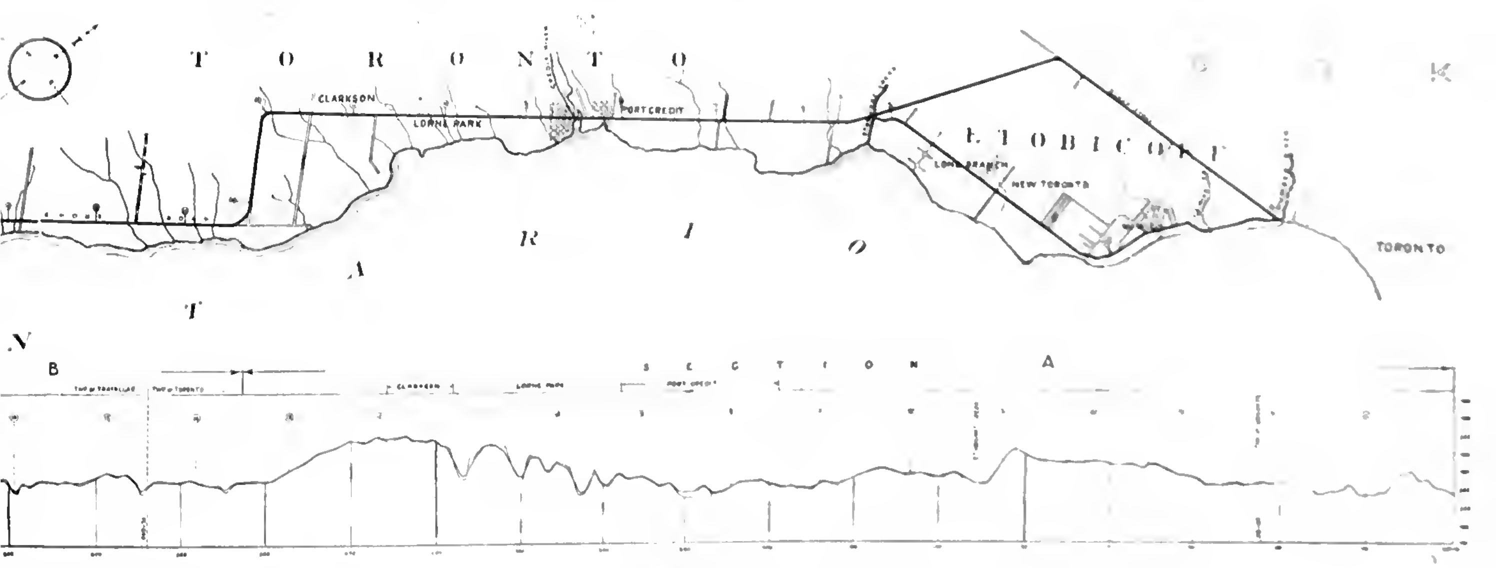
the large bins. In this way a trainload of dump-cars is loaded in less than half the time required to do this work by bucket and hoist, and the transportation capacity of this train is correspondingly increased.

Materials Supplied

The paving machines used are the Austin Cube type, purchased from Lecky & Collis; the crane used was supplied by the Brown Hoist Company, of Cleveland; dumping cars were supplied by the Dominion Wheel and Foundries Company, Toronto; the engine which operates the dump cars was purchased from the Canadian H. K. Porter Company, of Chicago, through the Construction Supply Company; the wheelbarrows used are the Meaford type, purchased through Wood, Vallance & Company; pumps for supplying water along the road are the Triplex type, manufactured by Smart, Turner & Company, purchased through A. R. Williams; the gasoline engines used on the pumps, Niagara Brand Spray Company, Burlington; scarifiers employed are the Austin type, Chicago, purchased through Mussens Limited; Rogers and Canada cement are both used for concreting; wire reinforcements were supplied by the Standard Tube and Fence Company, Woodstock; crushed stone by Rogers Supply Company; expansion joints by Bird & Son, Hamilton; tools used were bought from jobbers in general, or made by the Commission.

Profitable Year for Dominion Bridge Co.

The large earnings on shell orders are reflected in the annual report of the Dominion Bridge Company for the year ended 31st October. The net profits totalled $1,344,347, an increase of $714,379, and the largest recorded. These are after writing down depreciation on plant and machinery. After distributing 8¾ per cent. in dividends and bonus, a total of $568,750, paying $13,910 in directors' fees, transferring $204,282 to reserves, and applying $174,580 to writing down the company's holdings of National Bridge stock to a nominal value of $1, a balance of $382,817 remained to be added to profit and loss account. Mr. Phelps Johnson, the president, states that the company have a controlling interest in the Montreal Ammunition Company and the Dominion Copper Products Company. The bridge and structural business was much better than was anticipated, the volume of this business entered the past year being 86 per cent. of the business entered during the preceding year. Much of this business was secured at good prices, as the company was in a position to give ex-



more than half completed—Many heavy grades reduced so that maximum is 4 per cent.—Six gangs building this road at rate of half mile a day ceptional deliveries to those requiring plants built quickly for war business. The large profits were due chiefly to the fact that "a number of large contracts which had been in progress for several years were fully completed and charged up during the year, and because an exceptionally large proportion of the business written was completed during the year, and the profits accruing therefrom taken promptly into the accounts. There is a marked revival in the demand for structural work, and it is anticipated that your shops at Lachine, Toronto and Winnipeg will be kept reasonably busy and at satisfactory prices.

"Construction on the Quebec bridge, in which contract your company has a half interest, has progressed favorably during the year. The north cantilever arm is now completely erected and the traveller is being taken down to be used for the erection of the centre span. The south anchor arm is also completely erected and is further advanced than was the north anchor arm at a corresponding period last year. Unless the present shortage of steel delays the manufacture of the centre span, or the Government should curtail appropriations for progress estimates, it is anticipated the steel work will be fully erected next season."

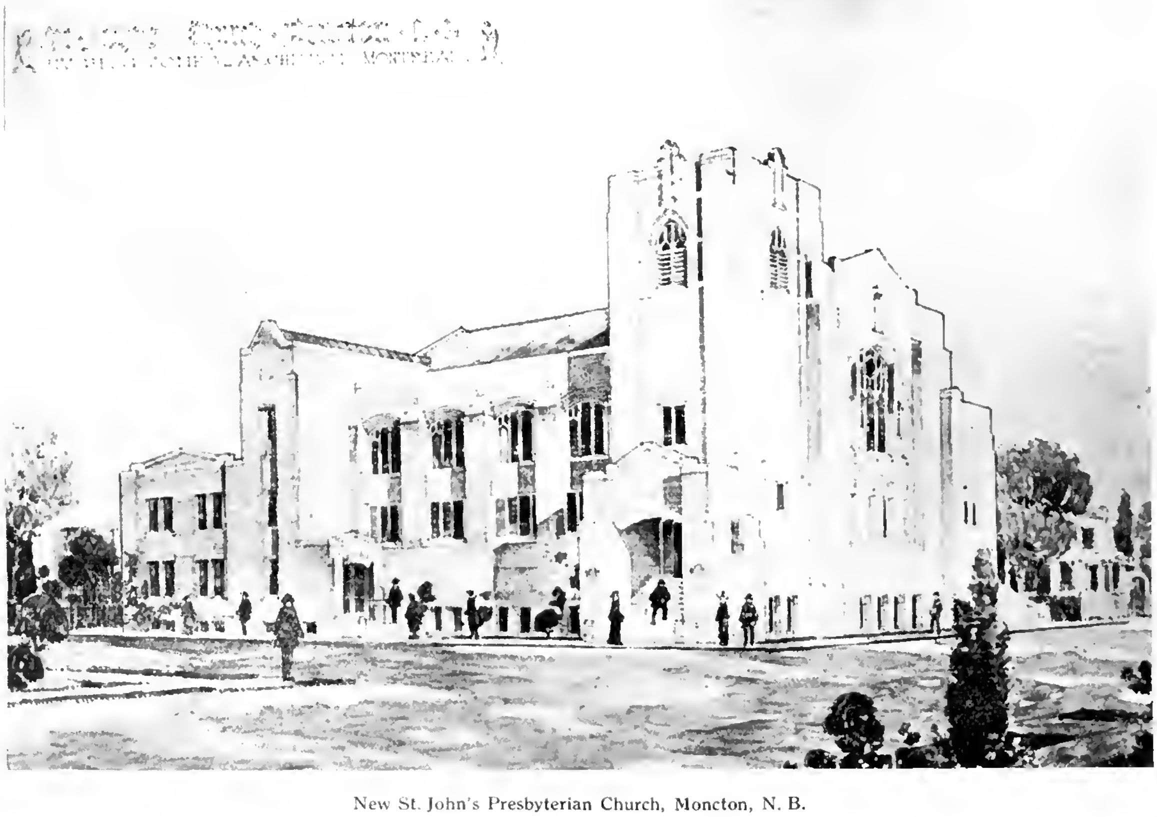
The company has opened a London office and endeavored to secure new foreign business. One contract had been executed for Madras, India.

Handsome New Church for Moncton, N. B.

The latest addition to Moncton, N.B., church buildings is the St. John's Presbyterian Church, erected at the corner of Alma and Victoria Streets. The design of the building was in the hands of Mr. Hugh G. Jones, architect, of Montreal, and the work was carried out under his supervision.

The exterior walls are of Wallace brick and Newcastle stone trimmings. The building is heated by a low pressure heating system, the air being exhausted by a blower connected by ducts to the front of the pulpit platform. The lighting is electric with semi-indirect fixtures. Seating accommodation is provided in the auditorium for 1,000 people, while a Sunday School at the rear provides accommodation for 500. A large assembly room has a seating capacity of 900, with a stage at one end and men's and women's retiring rooms adjoining. This hall is admirably suited for the social needs of the church.

The interior decoration and furniture was made from designs prepared by Mr. Jones. The total cost of the building was $80,000. E. B. Evans & Company, Montreal, were the general contractors, and the following firms had sub-contracts: Roofing and sheet metal, Sumner & Co., Moncton; plumbing and heating, F. J. Friedman, Montreal; millwork, Rhodes, Curry Co., Amherst, N. S.; plastering, A. W. Calkins, Moncton; painting, A. E. Metzler, Moncton; electric work, Perry Bros., Moncton; hardware, Lariviere, Incorporee, Montreal; stained glass, J. C. Spence & Sons, Montreal; organ, Canadian Pipe Organ Co., Ltd., St. Hyacinthe, Que.; seating and furniture, Berlin Interior Hardwood Co., Ltd., Berlin, Ont.

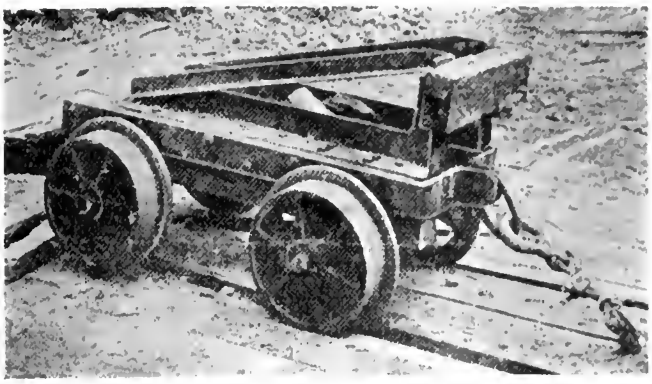


New St. John's Presbyterian Church, Moncton, N. B.

Barney Car for Hauling Wagons Out of Pit

The view shows a Barney car for hauling dirt wagons up to street level. The use of this car enables wagons to take a full load, and avoids the use of a snatch team.

The car runs on a narrow-gauge track of light rails laid on the incline. The nose of the car comes above the level of the rear axle of the wagon and thus when placed behind the axle pushes the wagon up the slope. A cable from the front of the car goes up the incline



Heavily built Barney Car for hauling wagons out of a pit.

to a snatch block near the top, where it passes through the decking and laterally downward to a hoisting engine. The car, as will be noted in the figure, is quite heavily made, and the butting block is well braced back to the main frame.

Toronto's Pavement Work Slightly Reduced

The following table shows the quantities of the various classes of pavement laid in the city of Toronto during the past year; also for comparative purposes the figures for 1914:

	1914		1915	
		Square		Square
Class of Pavement.	Lin. ft.	Yards.	Lin. ft.	Yards.

Building Activity in Sherbrooke, P.Q.

A report just issued from the building inspector's office in the city of Sherbrooke, Que., indicates that during the year 1915 forty-three building permits were issued, amounting to a total value of $350,000. Considering the depression generally felt in all trades during the past year, it is gratifying to note that building operations in this city were sufficiently active to keep all classes of labor well employed. That this was the case is indicated in the report. It is further stated that the outlook for the year 1916 is very encouraging, as buildings to the value of $250,000 are already contemplated. Adding to this the amount of construction work which is usually done during the year, the report concludes that there will be ample employment for all classes of labor.

Good Progress on St. Maurice River Dam

Work on the St. Maurice River dam being constructed for the Quebec Streams Commission by the St. Maurice Construction Company (contract sub-let to Fraser, Brace and Company), has made excellent progress. The site of the dam is many miles from the railway, and the contractors intend to use the river for thirty miles for the conveyance of supplies, machinery, etc., and a standard gauge line for the remaining twenty miles. About one and a half miles of this line has been constructed, and engines have been run on it. A very large quantity of ties have been cut; the timber on the whole right-of-way has been cleared; a large amount of crib work done; a complete telephone system installed; several log camps built; and terminal facilities at Manouan crossing completed. At one time the contractors had 500 men on the job.

Printing Error

In our last issue, in quoting materials used in the construction of the track platform, Yonge Street Grade Separation, we stated that 200,000 cu. yds. of reinforced concrete were used in the track slabs; this should have read 2,000 cu. yds.

Development of Canadian Highways

(Concluded from page 6)

tially macadamize the leading market roads in less than ten years.

National Progress and Production

I have journeyed in Northern Canada, along trails which, in fur trade, have been used by the Indians for centuries. A little work in removing fallen trees, in levelling knolls, filling low places, or improving the canoe landing, would have made the portage infinitely less laborious. But year after year the Indian has travelled these routes in shiftless abandonment to the obstacles imposed by Nature. As we regard the improvidence of the Indian with respect to his trails, so those who are accustomed to the splendid highways of Great Britain and France look upon the neglected and unimproved roads of this continent. They consider that only a very wealthy country, improvident of its resources, can progress under the handicap of bad roads. Those who have bad roads consider good roads an expensive luxury. But those who have seen the advantage of good roads, know that good roads are a necessity.

Standard Clay Products Calendar

Standard Clay Products, Limited, of St. Johns, P. Q., and New Glasgow, N. S., are distributing a very useful 1916 calendar, mounted on a background which illustrates various phases of their constructional operations and products. The sewer pipe plant of this company is claimed to be the largest in Canada.

Separate Manholes for Different Companies

The Quebec Public Utilities Commission, with the Dominion Railway Commission, sitting in Montreal on December 20, heard further arguments on the question of providing separate manholes for signal companies and for lighting and power companies in the underground conduits being constructed by the Electrical Commission. This is the first time that the Railway Commissioners have sat jointly with the Quebec Public Utilities Commissioners, the reason for this innovation being that as some of the companies affected hold Dominion charters, the question of jurisdiction may not be raised later in the courts. The Electrical Commissioners asked for sanction of plans for sections 6 and 7 in the business sections.

The Montreal Public Service Corporation, Bell Telephone, G. N. W. and C. P. R. telegraph companies, and others, asked that separate manholes be constructed, contending that there was danger of damage where only one manhole was made; on the other hand, the Electrical Commissioners argued that the present system was safe and that the danger was exaggerated.

Professor L. Herdt, chairman of the Electrical Commission, expressed the opinion that the best protection for the cables was to protect the cables themselves.

Sir Henry Drayton asked Professor Herdt if he had ever known a system of insulation that did not break down. The answer was "No." The chairman responded that if they had not an insulation that would not break down they could not say it was safe to put high potential wires near low potential wires. If the Electrical Commission were willing, however, to take the responsibility for any accident, he did not see why they should not be given an opportunity.

The question also arose as to the provisions of the provincial statute governing the construction of conduits. It was argued that the statute required double conduits, and Prof. Herdt retorted to this that the requirements of the statute were "absolutely obsolete to-day."

The joint commissions ordered their engineers to meet the engineers of the different companies affected and examine their plans. If the terms of the provincial statute needed amendment for safety, application could be made to the Legislature for that purpose.

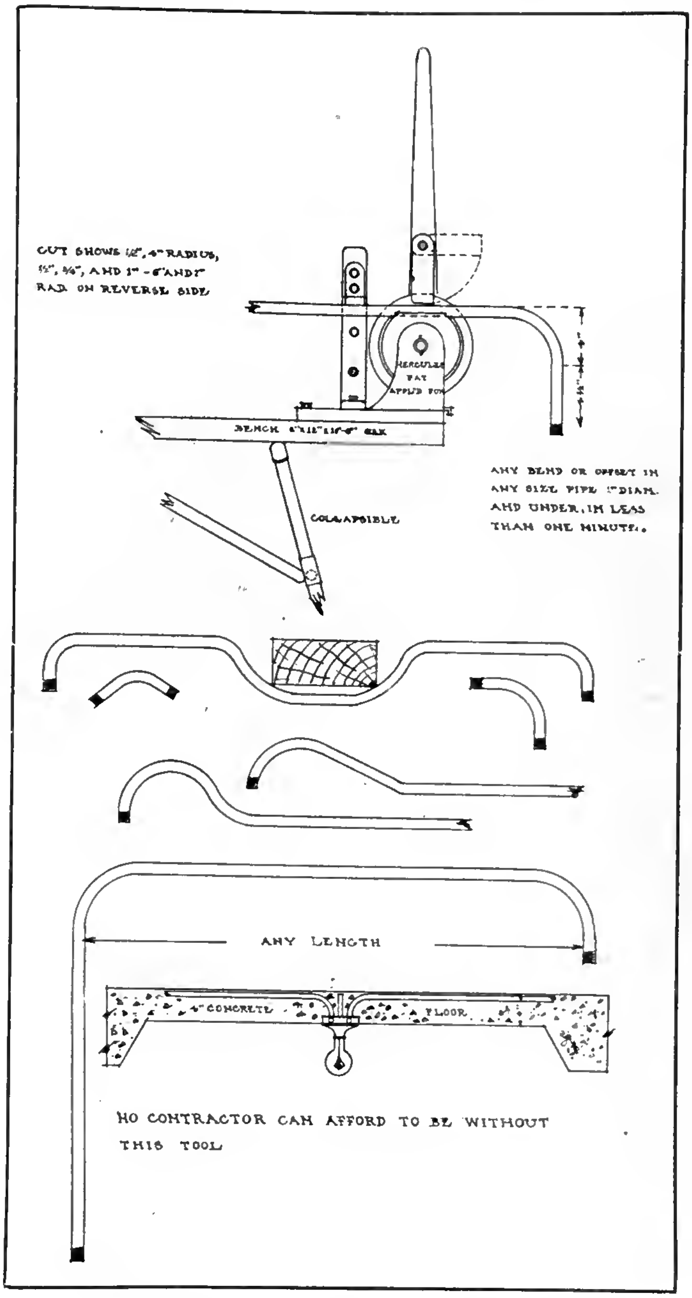
Efficient Pipe Bender

We illustrate herewith a new pipe bending device invented by Mr. G. E. Phillips, of the MacKenzie Electric Company, engineers and electricians, Sarnia, Ont. The basic principle on which this bender works is that the pipe is pulled around a grooved form, of the radius required, and not forced into shape with wheels or cams. The machine is very simple in construction and arranged to take the pipe from the side, which can be inserted or removed in an instant. With this bender it is possible to make a number of bends on one piece of pipe—bends and offsets being absolutely perfect.

The inventor claims a very considerable saving by the use of this equipment. On one job alone, which required all bends to be 4 inches radius, it saved 35 per cent. of the time and paid for itself just twice over. On any job where the contractor's time runs to as much as $150 the price of the machine can be saved in time gained. There is no guess-work about it. Pipes up to 1 inch can be bent cold and single groove machines for work up to 2½ inches will also be covered by this line, but the pipe will have to be heated before placing in the groove. This, however, will give a perfect bend without any flats or kinks whatever.

The proper way to rig up one of these machines is to have a 12 foot 2 inch plank 12 inches wide on a collapsible pipe frame. Put the bender on one end and the pipe vise on the other. The supply of conduit to be worked goes on the cross-bars of the frame under the bench. This helps to keep the bench down steady and the material is within reach. One-half inch to 1 inch bender weighs 75 pounds and, of course, cannot be used otherwise than on a plank.

If the saving on small jobs is so considerable it may easily be seen how efficient this machine would be on a job such as, for example, the new Union Station, where the amount of bending required is so considerable. Two or three of these machines would save hundreds of dollars in time and in addition every bend and offset would be perfect.



New pipe bending device—the invention of G. E. Phillips, Sarnia, Ont.

The Martin-Senour Company, Limited, Montreal, held a sales convention from December 13 to 16. The sessions were held at the Place Viger Hotel and at the paint and varnish factories, the delegates being welcomed by Mr. W. H. Gerke, the general manager. The subjects discussed related to advertising, salesmanship, agencies, price lists, policy, etc. On December 15 the usual "family dinner" was held at the Canada Club.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

Every day brings fresh evidence that the viewpoint of the Contract Record on certain vital questions that have been touched upon in previous issues under this heading coincides with the sentiments of thinking business men. It is further gratifying to note that even the Conservative papers throughout the Dominion are demanding an investigation into conditions surrounding various munitions contracts.

* * *

> The German prisoners of war at Montreal refused 400 pounds of turkey purchased for their Christmas dinner, ordered it taken away, and sent for a load of geese instead.—Exchange.

And I suppose the goose was served them. What a lot of simpletons we Britishers are. Given my way I would have served them lead in place of turkey.

* * *

We shall never sheathe the sword until Belgium recovers in full measure all, and more than all, that she has sacrificed, until France is adequately secured against the menace of aggression, until the rights of the smaller nationalities of Europe are placed upon an unassailable foundation, and until the military domination of Prussia is wholly and finally destroyed.—Premier Asquith.

* * *

The Minister of Finance hints at another War Loan of \$300,000,000. Bring it along, Mr. Minister. The Canadians will take care of it provided it is for the benefit of the Empire. In the words of the song—

"We didn't want to fight, but by Jingo! now we do
We've got the men, we've got the guns, and got the money too."

* * *

Major-General Bertram has taken all the alleged sins of the Shell Committee on his shoulders and gone south in search of new health. On his way he passed through Toronto, where he was able to sit up and talk about a column and a half to The Globe. Possibly he figured that giving his side of the story publicity through the Liberal organ would leave it free from partisan flavor and give the people of Canada an unprejudiced view of a great patriot who has been misunderstood and misrepresented. Anyway, he, by his own announcement, stands before you a man who rose from mechanic to manufacturer; who offered his services to his country and was made chairman of the Shell Committee. He awarded all the contracts, and was responsible for the Committee in every way. He alone awarded contracts to the amount of \$345,000,000, and doing it made a saving to the British War Office of \$42,000,000. And after doing all this he has been criticized! Do you wonder that he picks out a Grit newspaper and cries through its columns, "The attacks are not fair. They are breaking my heart."

* * *

Surely Sir Robert Borden will not allow that great heart to break. He has been loyal to his country, to his King, and to Sir Sam Hughes. For does he not quote Sir Sam's instructions "No politics—no graft"? And do we not know out of his own mouth that he made them his watchword and reply? And yet his hard-hearted leader sits idly by while leading Conservative papers like the Ottawa Journal, the Hamilton Spectator, and the Montreal Mail clamor for explanations. Surely the Premier should be able to see that a thorough investigation into the workings of General Bertram's committee would not only clear that gallant officer of the attacks that are breaking his heart, but would also prove once and for all that Canada is not and never has been the home of the profiteer. For to Canada's mind, as well as to the mind of the chairman of the Steel Company of Scotland, "there is something absolutely revolting in the idea of anybody actually making profits out of the nation's agony."

* * *

And though General Bertram may be staggering south with the entire weight of the Shell Committee on his shoulders, it is to Sir Robert Borden and his Government that the public look for explanations. The Government appointed the Shell Committee, and even if it acted in behalf of the Imperial authorities and took its instructions from them it represented the Canadian Government in every transaction in which it took part. It was the servant or agent of the Canadian Government and to its employer we must look for explanation of its actions.

* * *

So far Sir Robert Borden has taken no action in regard to the matter. He was heard from once in regard to the F. P. Jones incident, or chapter of incidents. His Government has appointed Sir Charles Davidson as official investigator of war contracts, but apparently his powers only extend to contracts for materials to be paid for out of the Dominion treasury. The order in council appointing the Commission reads "concerning the purchase by and on behalf of Your Royal Highness's Government." Consequently it would appear that as the shells were purchased for the Imperial authorities the shell contracts do not come within the scope of Sir Charles Davidson's labors. If this interpretation is correct the Government is all the more to blame for its silence. It was supposed that Sir Charles, with his investigations of spavined horses and poulticed drug bills, was simply clearing the decks for the heavier work. Now we are left to believe that with the "war baby" lying in its unnamed grave, General Bertram hurrying south with his failing health and breaking heart, and Wall Street boosting stocks by reports of enormous war profits, no provision has been made for clearing the matter up in any way whatsoever.

* * *

What use, then, to talk about taxing war profits? Without an investigation how are we to know that there are any profits to tax? General Bertram claims that he got the shells made for \$42,000,000 less than the estimates of the British War Office. Can it be possible that his one sin was too much economy, and that the impoverished contractors are really entitled to allowances from the Patriotic Fund? Was the man who had a half a million to spend on a plant with which he offered to make shells at cost really asking more than contract prices? Are all those stories that come from Wall Street simply attempts to sell a little stock to tide over a losing season spent making munitions? If any or all of this is true surely others besides General Bertram are entitled to the credit that only an investigation can bring.

* * *

But on the other hand, if the charges mentioned by the Montreal Mail have foundation it is the public and not the committee or contractors who are entitled to explanations. The Mail in criticizing General Bertram's open letter to Sir Sam Hughes says in part "It is with real reluctance that the Daily Mail suggests the incompleteness of what is termed General Bertram's 'valedictory.' A public duty, however, cannot be evaded, and it is a public duty to remind General Bertram that his statement, utterly lacking in detail and definiteness as affecting the criticism of the work of his committee, does not allay suspicion but tends to strengthen it. Major-General Bertram has been accused of enriching his private interests from business placed by the Shell Committee under his direction. He has been accused of showing favoritism in the distribution of shell orders, and of allowing prices to the manufacturers (including his own concerns) out of all proportion to the cost. Not one of these charges did he deal with in his valedictory, except in relation to the price of shells, and in this particular matter he withholds from the public the very information it desires." These are warm words. They are all the warmer that they come from a Conservative paper edited by M. E. Nicholls, a half-brother of Hon. W. T. White, Minister of Finance. It might be added, however, that in a more recent statement General Bertram states that he has only one share in the John Bertram and Sons Company, Dundas, Ont., which was the first firm to ship to England, and that he has never drawn a dividend from it.

* * *

For Mr. Flavelle's statement that contracts were to be taken from contractors General Bertram has an explanation. In fact, the Government apparently left him, not only all the work, but all the explaining besides. When the urgent call came from the trenches for high explosive shells the British War Office naturally turned to the Shell Committee. It had been doing wonderful work and saving immense sums of money. It had business sagacity that could almost equal Sir Sam Hughes' military genius. Exercising that sagacity, and realizing the need of securing these shells in the shortest possible time, the Shell Committee so placed these contracts that they haven't yet been filled. Consequently they are being recalled and placed with firms that can handle them.

* * *

It is wrong to criticize a sick man. But it is also wrong if there are Canadian soldiers filling graves in France because of blundering or profiteering in Canada. General Bertram has centred the Shell Committee in himself. He declares that he alone is responsible for its actions. He alone is attempting to make explanations. And the more explanations he makes the more evident it becomes that a thorough investigation is absolutely necessary.

* * *

One of our subscribers writes us that it is not the duty of trade papers to discuss politics or matters outside of the trade. He may be right. It is true that politics and politicians put the rules of trade carefully to one side before starting to run the biggest business in the country—the country's own business. It is true that no business man would think of running his business on the lines the country's business is run on. He would never think of putting a college professor in charge of a department he knew nothing about simply because he could make a good speech. He would never engage his employees for the simple reason that they had a pull with certain ward politicians. Consequently politics may be a trade apart. But the public have to pay the mechanics who work at this particular trade. Don't you think the said public is entitled to an occasional glance at what its workmen are doing? And how is it going to get it if some paper not "in the game" doesn't break loose occasionally? If a Grit paper criticizes, a Tory paper rushes to the rescue, and the issue is soon lost in the cloud of recrimination that is raised. So sometimes a trade paper stops to wonder why a Government cannot be run along honest business lines, and how long you or I would remain in business if we treated our customers the way the Government treats the public. It is our turn to furnish the public with its "look," and if our readers will bear with us yet a little longer they will discover that they are gazing on the body politic and seeing things, not as they are painted by a Government organ or the opposition critics, but exactly as they are.

* * *

It may be lese majeste to even mention the press censor. His work requires rare judgment and tact. He shows it every time he moves. His attention appears to have been called to this column, but as discussion of things political, including politicians, is allowed under the rules and regulations governing his department, he was powerless to blue-pencil a single sentence. However, you can't keep an industrious chap from doing something. And our censor is industrious. So he picked out certain and sundry paltry paragraphs in our news columns as inimical to the safety of the Empire. With an iron hand he wielded the pen that deprived the public of information as to where a few shell-boxes are being made. The Germans probably looked to the Contract Record for this information, as since its publication was prohibited not a single copy has been sold in Germany. And with this tremendous leak stopped could not the censor find time to look into the ways and works of one Henri Bourassa? If he publishes the stuff charged to him he would appear to be entitled to board and lodging in the internment camps. Then there is "The Hibernion"—a Yankee publication owned by the Germans and edited by a hyphenated chap. I heard a good Irishman discussing it and its editor the other day, and any publication that causes an honest man to use such language is certainly not fit reading for Canadians. Perhaps in the lull following his last grand work the censor can find time to take a look at it anyway.

* * *

When the cry went forth that this was a war of munitions Australia promptly began to mobolize its state-owned shops for munitions work. Did Canada do likewise? No; Canada—or rather the Canadian Government—promptly sidestepped by handing over the Transcona shops to a private syndicate which is doubtless doing a nice business at a nice profit. Had the Government been big enough to seize an opportunity it could have fitted up the Transcona shops with shell-making machinery at a cost of about $100,000, hired the best mechanics in the country, and turned out at least 5,000 shells per day. Moreover, it would then have been in a position to judge from its own experience just what price should be paid for shells. It would have had at first hand information which would have ended profiteering before it started. But probably the entire cabinet were busy making speeches when the opportunity offered. High-explosive speeches had to take the place of high-explosive shells.

* * *

Britain is said to have black-listed certain United States firms suspected of being affiliated with the Empire's enemies. And from the way the Kaiser's friends in the republic across the way have acted since the war began you would naturally expect the old land to be a bit careful as to whom she deals with. Canadians should follow suit. We have no quarrel with the United States. But within her borders are large numbers of the hyphenated, who are all the more dangerous that they are allowed at large among civilized people. Canadians should be careful that no business of any kind should be placed with them, either now or after the war.

* * *

It is reported that A. D. Foster, of King's, N. S., and W. F. Garland of Carleton, Ont., who were compelled to resign their seats in the House of Commons on account of inproper conduct in connection with Government contracts, will seek re-election in their constituencies. This puts the Conservative party in a quandary. The Government of course cannot attempt to accept those discredited men as its candidates, and yet it fears that either or both of them may by reason of personal popularity draw off enough votes from the regular candidate to elect a Liberal candidate. Pretty game, politics, isn't it? It is apparently so full of trickery that most of the players do not entirely blame a man who oversteps the rules and cheats a bit. But the government cannot afford to stand idly by. It must put up regular candidates, and if it cannot whip its followers into line it must take the consequences. Moreover, if either of the offenders should happen to be elected he should be ostracized at Ottawa and made to feel that bleeding the people he was elected to represent is something more than a political misdemeanor.

* * *

The protection of the new industries created by the war and its consequent shell orders is to be made the subject of a report from the Economic and Development Commission. And that report will require the closest scrutiny when it is presented. Even in official Ottawa it is admitted that prices obtained by some manufacturers have been sufficiently high to permit of the scrapping of their plants when the war is over. Of course if these plants can be kept going as business propositions, right and good. But the public will hardly stand for their being fed on Government pap. They've heard so much about munition profits that they'll want to know when the war is over that every Government dollar goes to the man who has fought for his country or those he has left behind him. He who has stayed home and made money will receive scant consideration.

* * *

When Tommy comes marching home he is going to ask the Government if it permitted the handing around of shell contracts "to prevent commercial depression" while his comrades were dying in the trenches for lack of the shells. Will the Government have its answer ready?

SEARCHLIGHT.

Obituary

Mr. John P. Longard, senior partner of the plumbing firm of Longard Brothers, Halifax, N.S., died suddenly recently. Longard Brothers is the oldest business in Halifax. It was founded 103 years ago by the grandfather of the late Mr. J. P. Longard.

The death occurred on December 18th of Mr. William Westlake, of Whitby, Ont. Before he retired from business fifteen years ago Mr. Westlake was a builder and contractor. He erected many buildings in Whitby, Oshawa, Bowmanville, and the surrounding country. The late Mr. Westlake was born in Yorkshire, England, and came to Canada when ten years of age.

Mr. Saxon F. Shenstone, Treasurer of the Dominion Radiator Company, Limited, Toronto, died quite suddenly on the morning of Christmas day. Mr. Shenstone was born in Brantford thirty-seven years ago, and was a son of Mr. Joseph N. Shenstone, Treasurer of the Massey-Harris Company. He began his business career in Hamilton, and continued it in Chicago, returning to Toronto and joining the Dominion Radiator Company seven years ago.

Mr. Graham Fraser, the father of the iron and steel industry in Canada, died suddenly on Christmas day at his home in New Glasgow, N.S. In 1872 Mr. Fraser and Mr Forrest McKay established the Hope Iron Works. When the wooden shipbuilding declined, and there was no more demand for the iron knees, they took up steel-making, and were the first to make steel axles in Canada, creating the steel industry in this country. In 1881 they formed the Nova Scotia Steel Company. Later on others became associated with them, the company acquired coal mines in Cape Breton, the ore deposits in Newfoundland were developed, and the company known as the Nova Scotia Steel and Coal Company came into being.

Pro Patria

Lieutenant Henry Hadley, late engineer of the city of Verdun, P. Q., has been attached to the 148th Battalion, Montreal. He was born in Montreal and educated at the High School and McGill University. He graduated from McGill in 1906, taking the degree of Bachelor of Science

Lieut. Henry Hadley.

in Civil Engineering, and resigned from the position of city engineer of Verdun to go to the front. Mr. Hadley has always been active in athletics, especially in paddling, rowing and boxing, being a well-known member of the M. A. A. A. and Grand Trunk Railway Boating Club. He has also been a provisional lieutenant of the 13th Dragoons since 1914.

Personal

Mr. Mervyn J. Allan, manager of Rocmac Roads, Limited, Toronto, for the last three years, has resigned to accept another position.

Corp. J. J. A. Gillies, a prominent young civil engineer, and a nephew of J. A. Gillies, K.C., French Consul, of Sydney, N.S., is now on active service in France. Corp. Gillies formerly carried on the activities of his profession throughout the Maritime Province and parts of Ontario.

Mr. F. P. Jones, General Manager of the Canada Cement Company, has just been elected a member of the board of directors of the Dominion Steel Corporation. It is also stated that he will probably succeed Sir William Van Horne as Vice-President of the corporation.

Mr. Norman Murray, for the last few years Town Engineer of Weyburn, Sask., is leaving for his old home in Scotland, and will obtain a commission in the Royal Engineers. Mr. R. S. Asher, formerly of the Town Engineer's staff, has just been promoted to a captaincy in the Royal Engineers in England, having left to join that corps on the outbreak of hostilities.

Mainly Constructional

East and West—From Coast to Coast

The Central Engineering Company, Limited, Montreal, have registered.

The M. J. Stack Paving and Construction Company, Limited, of Montreal, have registered.

The Canada Cement Company, Limited, is building an electric furnace at its Montreal plant.

The Shawinigan Electric Metals Company, formed to manufacture metallic magnesium, is constructing a new plant.

The Canada Cement Company, Limited, are extending the scope of this business. Among other lines, they will manufacture and deal in iron, steel, and all other metals.

Recorder Geofrion, in the Recorders' Court, Montreal, has decided that workmen can recover against the owner of a building when they fail to secure their wages from the contractor.

A. J. Flemming and H. G. Stewart have registered at Montreal, and will carry on the business of electrical engineers under the firm-name of the Engineering Company of Canada, Reg.

The Medicine Hat Pump and Brass Company are feeling the pulse of improving business. At the present time they have two hundred orders on hand for their pumps, and are employing over fifty men.

Canadian Steel and Brass Products, Limited, is the name of a new Toronto concern with a capital of five hundred thousand dollars. The provisional directors are A. Ogden, A. T. Bowlby, and G. Prior.

The Canadian Car and Foundry Company has secured an order for nearly two thousand freight cars, valued at about $2,000,000, for the French Government. Work on the order is to be started at once.

Mr. J. C. Stewart, head of the Canadian Stewart Company, who is in Toronto superintending the closing up for the season of the harbor works, expresses himself as satisfied with the year's work on the new harbor.

The ninth annual meeting of the Nova Scotia Society of Engineers lately in session at Halifax elected the following officers: President, J. L. Allan; First Vice-President, A. J. Barnes; Secretary-Treasurer, D. McD. Campbell.

Mr. John Quinlan, president, and Mr. D. K. Trotter, secretary, of the Montreal Builders' Exchange, represented that body on a large deputation which waited on Sir Lomer Gouin asking for a reform in the methods of governing the city.

An order for a large number of new locomotives for the National Transcontinental Railway has been given by the Dominion Government. This has been made necessary by the prospect of an enormous wheat traffic, estimated at approximately one hundred cars a day.

The Railway Commission of Ottawa has issued an order for the construction by the Toronto, Hamilton and Buffalo Railway of a new highway bridge in Hamilton carrying the line of King Street over the railway tracks. Seventy per cent. of the cost is to be borne by the company and 30 per cent. by the city.

The Bricklayers' Union, which financially and numerically is the strongest labor body in Western Canada, held its annual meeting in Winnipeg on December 27. The following officers were elected: Thomas Williams, president; Joseph Currie, vice-president; Joe Coulter, business agent; E. S. Jackson, treasurer.

The Electric Welding Company of Toronto, Limited, is the name of a new concern with head office in Toronto and a capital of $40,000. The provisional directors are W. H. Irving, H. H. Davis, and J. R. Rumball, all of Toronto. The company will carry on the business of electrical, mechanical, hydraulic, and civil engineers and contractors.

A paper on "Concrete T-Beams" by Mr. E. G. W. Montgomery, of the Highway Department of the Government of Saskatchewan, will form the principal attraction on the programme for the next meeting of the Regina Engineering Society. The meeting will be held in the Commercial Club at 8 o'clock on the evening of January 6, and will be preceded by a luncheon at 6.30 p.m.

The report of the committee of engineers appointed by the Calgary branch of the Canadian Society of Civil Engineers to investigate the charges made by Alderman A. W. E. Fawkes with respect to the work of the City Engineer, Mr. G. W. Craig, on the construction work of the Centre Street Bridge, Calgary, fully vindicates Engineer Craig, finding the charges made against him unjustified.

All the plans, profiles and field work records of the proposed new three-million-dollar Elbow River water works system, Calgary, Alta., which cost in the neighborhood of $10,000, are missing from the water works vault. A letter from Buffalo, N.Y., signed Oleson, says the writer overheard a plot to destroy these data in order that the men in the surveying department might have another year's work.

In the opinion of Commissioner Garden, the city of Calgary was badly "stung" by the contractor who put in the old pier under the Ogden traffic bridge. This pier rested on the soft earth of the river-bed, and in consequence settled when the July floods washed the bottom from under it. The city is replacing it by a new pier at great trouble and expense. In order to secure a sure foundation, the new pier has to be carried down some twenty feet further than the old one.

The Dominion Bridge Company, of Montreal, are setting an example in the way of patriotism which it is to be hoped will be emulated by many other firms who are making large profits out of war orders. At their annual shareholders' meeting on December 16th the following resolution was passed: "Resolved, that the meeting approve and authorize a contribution to the National Canadian Patriotic Fund for 1916 of two per cent. of the gross amount received on ammunition orders to the end of the calendar year."

The township Council of Sydenham, Ont., are taking up the matter of improved roads, and will take advantage of the plan available under the Colonization Roads Act, by which the Provincial Government stands half the cost of building main roads. The amount suggested to be spent next year is $2,000, to which the Government is expected to add another $2,000, and with this amount it is proposed to improve the three main roads—the Owen Sound-Meaford road, the Derby line, and the Lake Shore-Garreyowen road.

Commissioner Wigmore, of the St. John, N.B., City Council, showed his colleagues two pieces of lead weighing together more than fifty pounds, encrusted and rusty, which had been taken out of the 12-in. main that is being cleaned—the last of the series of city pipe-lines from Little River. These large pieces had been at some time or other poured into joints of the pipe while being repaired and had "run" on the inside of the piping. The wastefulness of such methods of repairs was shown in the fact that the incrusted part alone contained more than enough lead to solder properly any 24-in. joint.

Mr. E. B. Ford, chief engineer for Vancouver and district for the Great Northern Railway, has completed the work of driving test piles in the site of the foundation of the station which the railway company proposes to erect in False Creek, B. C. Mr. Ford states that as the result of these tests it is known that piles of a length ranging from 40 to 60 feet will be necessary. These will be driven below the level of permanent saturation, and because they will always be wet they are expected to last for a long time. Fir is the wood selected. On top of these piles concrete will be poured, and the granite base of the station will be built on the concrete. Mr. F. L. Townley, the architect of the station, is expected to return to Vancouver from the company's head offices at St. Paul later in the week.

The Union Cement Company, of Owen Sound, Ont., have received an order for approximately one hundred thousand barrels of cement—or the entire supply for the different departments of the city of Toronto for the year. In order to get the order under way in time for the opening of the season's work in the city the big cement mill will be started on Feb. 1st, several months earlier in the season than usual. Another contract for forty thousand barrels has been landed. With these two orders on hand, together with their regular trade, the company are looking forward to a large season's business. A staff of from 80 to 90 men is required when the plant is in operation, and this is another indication that employment will be plentiful in Owen Sound during the year 1916. The Union Cement Company have severed their connection with Alfred Rogers, Limited, and will hereafter be an independent concern.

The Ottawa Journal calls attention to the fact that December 22nd marked the fifty-sixth anniversary of the cutting of the first sod for the foundations of the Dominion Parliament Buildings, the ceremony of laying the corner-stone by Edward VII, then Prince of Wales, taking place a year later This fine example of Gothic architecture has already become historic, and visitors who come to see it go away with their minds enriched. The architect was Thomas Fuller, an Englishman of great ability who had settled in Toronto. When plans were called for Fuller's were easily the best, and little time was occupied in getting to work. When he had finished this work, in 1867, he won the prize for the best design for the Legislative Buildings at Albany, and removed there to superintend this other magnificent work. He remained in the United States until 1881, when he was invited to become the chief Dominion architect, succeeding the late Mr Scott, who had been chief architect since 1871. He occupied this position until 1897, when he resigned and Mr. Ewart was appointed in his stead. Mr. Fuller was an old man then, and died about a year after.

One of the largest, if not the largest, pipe-line and gas propositions of the continent has just been consummated by the disposal in New York of the bonds of a project to pipe gas from Southern Alberta to Winnipeg, Brandon, Regina, Moose Jaw, and all other important towns along the line of the Canadian Pacific in the western prairies. Behind the proposition are Calgary financial men, the engineer for whom is Mr. J. L. Kempher. It is announced that work on the project will be commenced during the first week of January, and that the construction will cost approximately ten million dollars, consisting of two pipe-lines with great compression stations, and that the work will employ a large number of men as soon as it is fully under way. The Calgary men conceived this idea of piping gas on this, probably the largest gas project yet attempted so far as length of piping is concerned, some months ago. The proposal was gone into thoroughly, some of the best engineers of the United States and Canada reporting on its feasibility before any definite steps were taken. Among the engineers were representatives of Ford Bacon & Davis, engineers for the Pennsylvania Gas Company, and the People's Gas Company of Philadelphia and Pittsburgh. Their reports showed the scheme to be practicable, and then negotiations were begun with Winnipeg and an offer was made to that city to supply gas at a certain figure which could not yet be ascertained. Winnipeg, it is learned, agreed to accept the offer if the city attorneys were assured of the financial success of the enterprise. This is now given by the taking over of the bonds by one of the largest financial firms in New York.

The Croaker

Once on the aidge of a pleasant pool,
Under the bank where 'twas dark and cool,
Where bushes over the water hung,
And rushes nodded, and grasses swung,
Jest where the crick flowed outer the bog,
There lived a grumpy and mean ole frog,
Who'd set all day in the mud and soak
And jest do nothin' but croak and croak,
Till a blackbird hollered, "I say, yer know,
What is the matter down there below?
Are you in trouble, er pain, er what?"
The frog sez, "Mine is a orful lot;
Nothin' but mud and dirt and slime
For me ter look at jest all the time
It's a dirty world!" so the old fool spoke,
"Croakity-croakity-croakity-croak!"

"But yer lookin' **down!**" the blackbird said;
"Look at the blossoms overhead,
Look at the lovely summer skies,
Look at the bees and butterflies;
Look **up,** old feller. Why, bless yer soul,
Yer lookin' down in a muskrat hole!"
But still with a gurglin' sob and choke
The blame ole critter would only croak.
And a wise old turtle, who boarded near,
Sez to the blackbird, "Friend, see here:
Don't shed no tears over him, fer he
Is low-down, jest 'cause he likes ter be;
He's one er them kind er chumps that's glad
Ter be so mis-rable-like and sad;
I'll tell yer somethin' that ain't no joke,
Don't waste yer sorrer on folks that croak."

—From "New Age"

Trade Publication

Condenser Work—The Wheeler Condenser and Engineering Company, Carteret, N. J., are distributing three new books—(1) Steam Tables for Condenser Work, third edition; (2) Psychrometric Tables for Cooling Tower Work; and (3) a combined cloth-bound volume of these two books. Paper-bound copies of these books are available without charge to any engineers who may write the company.

An Asphalt Primer

The Barber Asphalt Paving Company, Philadelphia, have issued an interesting little booklet entitled "The Asphalt Primer and Colloidal Catechism." This is an explanation, in question and answer form, of the principles of colloidal chemistry as applied to the paving industry. An asphalt mixture, it is explained, must be regulated on the basis of surfaces and films. The presence of colloidal matter such as has been discovered in Trinidad asphalt enormously increases the surface area of the aggregate, and results in a more closely-held and thicker film of bitumen about the particles of the aggregate. The primer is illustrated with wood cuts of ancient and modern highway building

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Burlington, Ont.
Tenders will be received by the Town Clerk, James S. Allen, on the supply of 850 feet of 30-inch concrete pipe.

Calgary, Alta.
Plans and profiles have been prepared by the City Engineer, G. W. Craig, for the construction of a waterworks system, estimated to cost $3,000,000.

Kincardine, Ont.
The Town Council are considering the construction of a reservoir and a pipe line. Engineer, A. Ingram. Estimated cost, $5,000.

Listowel, Ont.
The Town Council are considering the construction of a pavement on Main St. Clerk, William Bright.

North Vancouver, B.C.
Estimates are being prepared with regard to the construction of a pumping station for the supply of water to the Capilano Section. Engineer, A. M. West.

Ottawa, Ont.
The City Engineer, F. C. Askwith, is preparing plans for a driveway to be constructed along the Rideau River. Work on grading will start at once by day labor.

Quebec, Que.
Work by day labor is about to start on waterworks and drainage construction, estimated to cost $25,000. Waterworks Engineer, T. A. J. Forrester.

Toronto, Ont.
The Board of Control will receive tenders until January 11th for the supply of special iron castings for the Main Pumping Station. Specification at Room 12, City Hall.

Vancouver, B.C.
Work will start in the spring on the construction of the Stanley Park Sewer for the Vancouver & Districts Joint Sewerage & Drainage Board, 718 Granville Street. Engineer, A. D. Creer. Approximate cost, $130,000.

The City Council are negotiating with the Hastings Mill Company with regard to repairing the Seymour Pipe Line Road, of which the Company are the principal users. Estimated cost, $6,560. Engineer, F. L. Fellowes.

Railroads, and Bridges Wharves

Dunville, Ont.
The proposed work at Dunnville will include the construction of a ferry slip, turning basin, and considerable dredging in the mouth of the Grand River. This latter will be done by the Dominion Government under supervision of A. R. Dufresne, Assistant Chief Engineer of the Department of Public Works.

Hamilton, Ont.
The Toronto, Hamilton & Buffalo Railway, Hamilton, have been authorized to construct a bridge on King Street over the tracks.

Moncton, N.B.
The Moncton Tramways, Electricity & Gas Company, Limited, 38 Mechanic Street, will start work in the spring on the construction of 1½ miles of track. General Superintendent, A. B. Coryell.

St. John's, Que.
Plans and specifications for the construction of a bridge have been received by the Town Council from the Provincial Government. Clerk, J. A. Raymond.

Toronto, Ont.
The Board of Control will receive tenders until January 11th for the supply of red lead paint required for the Bloor Street Viaduct. Specifications at Room 12, City Hall.

CONTRACTS AWARDED

McNab Township, Ont.
The Township Council have let the contract for the construction of a bridge over Waba Creek to John Stewart, Waba. Wood construction.

Quebec, Que.
In connection with the construction of a dry dock for the Dominion Government Department of Public Works, the contract for glazing has been awarded to G. B. Mitchell, Jacobs Building, Montreal, and for the supply of coal and ash handling machinery to the Canadian Link-Belt Company, 1189 King Street West, Toronto, Ont.

Public Buildings, Churches and Schools

Alberta Province
Plans are being prepared by F. Blakey, Parliament Buildings, Edmonton, for the erection of an institution for the mentally defective.

British Columbia Province
The Provincial Government have decided to erect an institute for imbeciles. Minister, Hon. H. E. Young, Victoria.

Fredericton, N.B.
Tenders will be received until 4 p.m., January 18th, by R. C. Desrochers, Department of Public Works, Ottawa, for the installation of interior customs fittings. Plans and specifications with L. Yerxa, Caretaker, Fredericton, D. H. Waterbury, Clerk of Works, St. John, and at the Department. Specifications only at office of MacLean Daily Reports, Limited, 25 Charlotte Street, Toronto.

Listowel, Ont.
Interior repairs to the Methodist Church are being considered. Work will include a heating plant, leaded glass windows and decoration, and is estimated to cost about $9,000. Pastor, Rev. J. E. Millyard.

Manitoba Province
The erection of an institute for the deaf and dumb has been decided upon by the Provincial Government. Minister, Hon. G. R. Coldwell, Winnipeg.

Quebec, Que.
No tenders will be called for the seating required in connection with the school now being built at Seventh St. and Eighth Avenue for the Roman Catholic School Commissioners.

Saskatchewan Province
The Provincial Government have decided upon the erection of an institution for the blind. Minister, Hon. Walter Scott, Regina.

St. Catharines, Ont.
The Congregation of Haynes Avenue Presbyterian Church intend to build a hall in the spring. Work will be done by day labor under supervision of Thomas Mesler, 188 Queenston Street.

St. Marie, Que.
Repairs to the Roman Catholic Church are being considered. Work will include new flooring, electric lighting and painting. Curate, J. E. Teuiltant.

Toronto, Ont.
Tenders will be received until 4 p.m., January 10th, by R. C. Desrochers, Department of Public Works, Ottawa, for the erection of temporary Postal Station A at Bay and Front Streets. Steel truss and galvanized iron construction, concrete and brick piers. Plans and specifications at office of T. A. Hastings, Postal Station F, Toronto, and at the Department.

Tenders will be received until January 26th by E. F. Henderson, Chairman of the Sites and Building Committee of the Separate School Board, for the following:—(a) erection of St. Clare's School; (b) erection of St. Monica's School; (c) addition to St. Anthony's School; (d) addition to St. Joseph's School. Plans and specifications at office of the Architect, C. J. Read, 203 Confederation Life Building.

CONTRACTS AWARDED

Montreal, Que.
In connection with the presbytery now in course of erection on St. Joseph Boulevard for the Trustees of St. Pierre Claver Church, the contract for heating has been let to G. Champagne, 78a Inspector Street.

Montreal North, Que.
The following contracts have been let in connection with the Town Hall which is now being built:—carpentry, Bourgon, Gagne & Company, 1882 Notre Dame Street W., Montreal; brick work, C. Morin, 2572 Christopher Columbus Street; plastering, C. Malhiot, 535 Alma Avenue; painting, A. Wilton; roofing, heating and plumbing, Bastien & Vaillancourt, 962 Papineau Avenue; electrical work, J. A. St. Amour, 2171 St. Denis Street; architectural iron work, Montreal Architectural Iron Work Company, 157 Prince Street.

Portage La Prairie, Man.
The Department of Public Works, Ottawa, have awarded the contract for electric wiring and fittings to Houston & Company, 215 Saskatchewan Avenue, Portage la Prairie.

Roberval, Que.
The School Commissioners have let the contract for roofing, heating and plumbing in connection with the school now being built to A. Binette. Plastering, painting and electrical work not yet awarded.

Business Buildings and Industrial Plants

Hamilton, Ont.
The Hammant Steel Car Company are considering the erection of an addition to their factory on Kenilworth Avenue. Manager, J. Marsella.

The proposal to erect an abattoir will be considered in the year by the City Council. Clerk, S. H. Kent.

Leamington, Ont.
The Town Council propose to grant a site for three warehouses to the Rock City Tobacco Company, 224 Dorchester Street, Quebec, and have appointed a Committee to purchase it. Manager of the Company, W. Druin, Quebec. Approximate cost of buildings, $25,000.

Leonardville, N.B.
W. D. Welch has decided to rebuild his store and factory, but will not start work until the spring.

Levis, Que.
The Bell Telephone Company of Canada are considering the erection of an exchange building on Wolfe Street, and will have plans prepared. Local Manager, F. Belcourt.

Lion's Head, Ont.
The Lion's Head Milling Company propose to rebuild their flour mill.

London, Ont.
The Parnell Baking Company, 75 Bruce Street, contemplate the enlarging of their equipment. Work may start in the spring. Manager, E. Parnell. Estimated cost, $25,000.

Manitoba Province
The Provincial Government have secured a site for a Prison Farm and contemplate the erection of a number of buildings. Minister, Hon. T. H. Johnston, Winnipeg.

Moose Jaw, Sask.
The Robin Hood Mills, River Street W., Moose Jaw, propose to erect a number of flour mills in the Western Provinces.

New Westminster, B.C.
The City Council have had tentative plans prepared for a market building to cost about $35,000. Architect, F. G. Gardiner, 328 Third Street.

Ottawa, Ont.
Work is about to start on repairs to the plant of the Pritchard & Andrews Engraving Company, 269 Sparks Street. Owners will purchase material.

In connection with the addition now being built at the factory of the Capital Wire Cloth Company, Armstrong Street, most of the work will be done by day labor.

St. Catharines, Ont.
A. Puccini & Company, 55 Front Street E., Toronto, have had plans prepared for alterations to the Stevenson Building. Work includes concrete floors and removal of partitions. Architect, J. W. Siddall, Confederation Life Building, Toronto.

Toronto, Ont.
The addition which is now being built at the factory of the Canada Metal Company, Fraser Avenue, will be of brick and steel construction. Approximate cost, $10,000.

James A. Wickett Limited, Traders Bank Building, are receiving sub-tenders on all work and material required in the erection of a Hydro Transformer Station at St. Thomas. Tenders must be in by January 14th.

Vancouver, B.C.
Plans are to be prepared at once for alterations to a store at Hastings and Abbott Street for the Woodward Department Stores Limited. Tenders will be called during January. Estimated cost, $6,000.

CONTRACTS AWARDED

Brampton, Ont.
In connection with the addition now being erected at the factory of the Copeland Chatterson Company, the painting contract has been awarded to James Harmsworth, Brampton.

Fort Erie, Ont.
Work has been started on razing old buildings on Niagara Street preparatory to the erection of a bakery and residence for E. Hawkins. The general, carpentry and roofing contracts have been let to C. W. Taylor, Bridgeburg, Ont. Frame construction, concrete foundation, shingle roofing. Approximate cost, $5,000.

Montreal, Que.
Work has been started on the erection of a storage building for Matthews-Blackwell Ltd., Mill Street. The general contract has been let to P. C. Currans Company, 1002 Cartier Street, and the carpentry to Thomas Harrison, care of general contractor. Frame construction, concrete foundation, felt and gravel roofing. Approximate cost, $3,000.

In connection with the conversion of premises at 59 Park Avenue into a store for B. Dixon, 83 Craig Street West, the contract for roofing has been let to Richardson, Simard & Company, 745 Clarke Street, and the mill work to R. Macfarlane & Company, Ltd., St. James Street.

Ottawa, Ont.
In connection with the addition now being built at the factory of the Capital Wire Cloth Company, Armstrong Street, the contract for iron work has been awarded to the Canadian Agency & Supply Company, Booth Building, Sparks Street, and the brick work, concrete and roofing to the general contractors, Cuthbertson & Clark, 706 Echo Drive. Heating by owners. Plumbing and electrical work will be awarded in the spring.

Paris, Ont.
In connection with the factory now in course of erection for the Paris Wincey Mills Company, Limited, the plumbing contract has been awarded to Charles Taylor & Company, 12 Dalhousie Street, Brantford.

Sherbrooke, Que.
The following contracts have been let in connection with the machine shop which is being built for the Canadian Ingersoll Rand Company: roofing, Campbell, Gilday & Company, Limited, 793 St. Paul Street, Montreal; painting, Paquette & Son, St. Francis Street; heating, plumbing and sprinkler system, General Fire Extinguisher Company, 374 Beaumont Street, Montreal. Carpentry by the general contractor.

St. John, N.B.
The contract for steel work required in connection with the Young Men's Club which is now being built has been let to the Eastern Canada Steel & Iron Works, St. Malo, Que. Architect, R. A. Frechet, 30 Bonnacord Street, Moncton.

Vancouver, B.C.
The contract for painting required at the bank vault building which has been erected on Grandview Avenue for the Canadian Bank of Commerce has been let to the Vancouver Decorating Company, care of William F. Gardiner, 347 Pender Street West.

The Hudson's Bay Company, Georgia Street, have let the general contract for an addition to their store to the British Columbia Construction & Engineering Company, Fisgard and Douglas Streets, Victoria. Work will start at once. Brick construction. Approximate cost, $25,000.

Residences

Niagara Falls Centre, Ont.
W. C. Pretty, 751 Ferry Street, is considering the erection of a residence and garage to cost about $6,000. Work may start in January. No contracts yet awarded.

Ottawa, Ont.
Mrs. Charlebois, Springhurst Street and Beechwood Avenue, intends to rebuild her store and residence which were recently destroyed by fire. Frame construction. Approximate cost, $3,000. Work by day labor.

Plans are being prepared for a residence to be erected on Fentiman Avenue by F. Nunn, care of Ritchie & Nunn, 165 Sunnyside Avenue. Brick veneer construction, concrete foundation, shingle roofing. Contracts will be let for plastering, heating and plumbing. Estimated cost, $4,000.

The erection of a residence on Electric Street is being considered by Herbert

Cotter, 80 Vaughan Street. Double brick veneer construction, concrete foundation, felt and gravel roofing. Approximate cost, $4,000.

Tenders on brick work, roofing, plastering, painting, heating, plumbing and wiring required in the erection of a residence are now being received by the Estate of John O'Leary, 208 Laurier Avenue. Brick veneer construction, felt and gravel roofing. Approximate cost, $4,500.

Toronto, Ont.
H. B. Jackson, 134 Bracken Avenue, has commenced the erection of a residence, estimated to cost $4,500. Smaller trades will be let. Brick construction, shingle roofing.

Work has been started by A. M. Crawford, 44 Beech Avenue, on the erection of a residence. Smaller trades will be let. Brick construction, shingle roofing. Approximate cost, $3,000.

CONTRACTS AWARDED

Hamilton, Ont.
In connection with the residence which has been erected at Herkimer and McNab Streets for R. Kirkpatrick, the contract for heating and plumbing has been let to P. A. Moore & Company, 939 King Street E. Electrical work not yet awarded.

Lachine, Que.
B. Desmarais is building a residence on Aberdeen Avenue for George Marcil, 180 St. James Street, Montreal. Brick construction, concrete foundation, asbestos roofing. Estimated cost, $3,000.

Montreal, Que.
In connection with the residence which is being built on Delorimier Avenue for J. B. A. Aubry, the contract for painting has been let to Girard & Boucher, 291 Iberville Street, and the roofing, heating and plumbing to Vaillancourt & Bastien, 692 Papineau Avenue. Masonry, brick work and carpentry by the general contractor, J. Pilon, 2044 Bordeaux Street.

Work has been started by Anglin's Limited, 65 Victoria Street, on the erection of a residence on Draper Avenue for E. W. Herring, 2 McGill College Avenue. Tenders are now being received for roofing and electrical work. Brick construction, concrete foundation, felt and gravel roofing. Estimated cost, $4,000.

The contract for steel work required in connection with the flats which are being built on Grand Boulevard for G. N. W. Zwinge, 296 Madison Avenue, has been awarded to the Dominion Bridge Company, Limited, Lachine, Que.

The contractors for the residence which has been erected on Old Orchard Street for J. C. Rancourt, 115 Melrose Avenue, are as follows:—brick work, A. Pepin, 18 de Gaspe Avenue; roofing, F. X. Goudreau, 255 Visitation Street; plastering, Henry Dedewarder, 45 Pie IX Avenue; glazing and painting, J. H. Cox, 241 Melrose Avenue; electrical work, Simard & Fanteux, 77a Bourget Street.

Ottawa, Ont.
William O'Connor, 495 Somerset St., is building a residence in Ottawa East, estimated to cost $5,000. The contract for heating and plumbing has been awarded to J. P. Rand & Company, 775 Bank Street. Painting by owner.

The following contracts have been awarded in connection with the residence which is being built on Bethany Road for Victor Joyce, 162 Spadina Avenue:—general, carpentry and roofing, Charles J. Joyce, Somerset Street; brick work, Thomas Dean, 21 Stirling Street; heating, J. Cameron, 488 Lewis Street; plumbing, J. T. Blythe, Frank Street; electrical work, H. L. Allan, 377 Somerset Street. Brick veneer construction, stone foundation, shingle roofing. Approximate cost, $4,000.

The contract for plastering required at the residence which has been built on Brighton Street for H. Puddicombe, 410 Queen Street, has been awarded to J. Jarvis, 18 Fourth Avenue ,and the heating to the Capital Hardware Company, Bank Street.

Quebec, Que.
The contract for heating, plumbing and electrical work required at the residence which is being erected on Charlesbourg Road by Lavoie, Martel & Beaupre, First Avenue, Domaine Lairet, has been awarded to A. Noreau, Fifth Avenue, Domaine Lairet.

Sarnia, Ont.
McWater Bros., 254 Cromwell Street, have commenced the erection of a residence for Frank Williamson, 260 Maxwell Street. Frame construction, shingle roofing. Estimated cost, $3,000.

Toronto, Ont.
The contract for heating and plumbing required at the residence and garage which have been built at 35 Munro Park Avenue by R. E. Oliphant, 117 Willow Avenue, has been let to Stratton & Cook, 314 Lee Avenue.

Verdun, Que.
Work has been started by Anglins Limited, 65 Victoria Street, on the erection of two flats on Rielle Street for W. T. Tipping, 257 Gordon Avenue. Brick veneer construction, felt and gravel roofing. Approximate cost, $3,000.

Westmount, Que.
In connection with the residence which has been erected on Sunnyside Avenue for L. J. Ryan, 545 Notre Dame Street W., Montreal, the contract for mantel and tile work has been awarded to G. R. Locker Company, 143 Mansfield St., Montreal, and the hardware contract to Durand Hardware, 370 St. James Street, Montreal.

Power Plants, Electricity and Telephones

Brooke Township, Ont.
The Secretary of the Brooke Municipal Telephone Company, who are considering the extension of their system ,is R. J. Lucas, Watford, Ont. Manager, R. Chapman, Inwood, Ont.

St. Come, Que.
Work will start soon on the construction of an electric system for La Compagnie d'Energie Electrique. Particulars from the Mayor, Dr. Poliquin.

The Pas, Man.
The by-law authorizing the installation of a telephone system at a cost of $12,000 has been carried. Town Clerk, H. H. Elliott.

Fires

Brooks, Alta.
Fire has destroyed the pool room owned by W. R. Winters, and the store belonging to F. Ainlay. Total loss, about $10,000, partly covered by insurance.

Chatham, Ont.
The carriage works of William Gray, Sons & Campbell, Limited, 78 William Street, have been destroyed by fire.

Crow Lake, Ont.
The residence of James Mahan has been destroyed by fire. Loss covered by insurance.

Frome, Que.
Fire has totally destroyed the barn and outbuildings owned by Robert S. Chute. Loss partly covered by insurance.

Goderich, Ont.
Fire has entirely destroyed the barn belonging to Robert McAllister, Seventh Concession, W. Wawan.

Jamestown, Ont.
The factory of the Jamestown Table Company has been destroyed by fire. Loss, about $2,000, covered by insurance.

North Bay, Ont.
The store owned by Dole & Son has been damaged by fire.

Ottawa, Ont.
Fire has damaged the stores at 195-199 Bank Street, the property of S. A. Luke, 59 Rideau Street. Loss, about $4,000.

Princeton, Ont.
The flour mill owned by Maycock & Harris has been totally destroyed by fire. Loss, $10,000.

Saskatoon, Sask.
The storage building of the Northern Storage, 455 First Avenue N., has been completely destroyed by fire. Loss, $60,000.

St. Francois Xavier, Man.
The Roman Catholic Convent has been totally destroyed by fire. Loss, about $10,000.

Toronto, Ont.
The premises of the William Radford Company, 212 Adelaide Street W., have been damaged by fire. Loss on building and stock, about $6,500.

Weedon, Que.
The premises of the Weedon Chemical Company have been destroyed by fire. Loss, about $10,000, covered by insurance. The Company intend to rebuild immediately, and will require cement, steam boilers and chemical fabrication machinery.

Miscellaneous

Creemore, Ont.
John Cotril, Creemore, is in the market for two motors, 1 and 2 horse power, single-phase, 60-cycle.

New Waterford, N.S.
The Town Council propose to purchase a motor fire truck with engine and force pump. Estimated cost, $10,000.

Ottawa, Ont.
The City Council will call for tenders early in the year for the supply of stone for 1916. Engineer, F. C. Askwith.

CONTRACTS AWARDED

Peace River Crossing, Alta.
The Edmonton, Dunvegan & British Columbia Railway Company, Edmonton, have let the contract for oil drilling to J. D. McArthur, E.D. & B.C. Yards, St. Albert Trail. Work will start at once on the installation of drilling plant.

Terra Cotta Society to Advertise

Twenty thousand dollars will be spent next year in a national advertising campaign to educate architects and builders in the merits of terra cotta as a building material—that is, if the plans made at the annual convention of the National Terra Cotta Society, held recently at the Hotel LaSalle, Chicago, Ill., are carried out.

In the past few years especially, terra cotta has been forging to the front as a beautiful, economical and durable facing for building fronts and interior decoration. Those architects and builders who are more progressive than the rank and file—and a trifle more open-minded—have fully realized the merits of this form of decoration and are using it to advantage, securing artistic work of lasting quality at a cost that is pleasing to the average client. But this is not enough. Ignorance as to these merits on the part of the vast majority of those engaged in the building professions and trades, who should be more consistent users of terra cotta, has stood in the way of its advancement. It is to supply this lack of information, that the society has determined upon a nation-wide publicity campaign, the appropriation for which will, no doubt, be increased as the work develops. A committee was appointed to take the project in hand, the personnel of which has not as yet been announced.

President Fritz Wagner called the convention to order at the opening session, the usual procedure being followed, including the annual reports of the officers and various committees which had been appointed for the year just closing. A number of new committees were then appointed for which considerable work was outlined to be accomplished during the coming year, along lines of general interest to the society and the development of co-operation among the members in the industry.

On Friday evening, December 10, a banquet was held at the Hotel LaSalle at which Thomas Armstrong, of the Conkling-Armstrong Terra Cotta Company, Philadelphia, was toast-master. Short talks were given by a number of the members.

The election of officers was held on Saturday afternoon, December 11, Fritz Wagner being re-elected president. Thomas Armstrong was chosen as vice-president; Harry Lucas, of the Northwestern Terra Cotta Company, Chicago, secretary; and E. V. Eskensen, of the New Jersey Terra Cotta Company, Perth Amboy, N. J., treasurer. From fifty to sixty delegates were present at the convention, representing twenty-seven different companies.

The consensus of opinion of those present was that 1916 will be a very prosperous year in the industry. "The terra cotta trade has been greatly depressed," said one of the members, "but within the last month or so there has been rapidly growing evidence of returning activity. Building prospects are now excellent in all parts of the country."

Cement-Coated Piles Repaired Under Water

Wooden piles, wrapped with wire-mesh reinforcing and coated with concrete by means of a cement gun were used by the P. J. Carlin Construction Company in building the San Juan bulkhead in Porto Rico, and described by Mr. Carlin recently in the Cornell Civil Engineer. In applying the coating the piles were carried on roller supports 40 feet apart. As the concrete applied to each pile was 2½ inches thick, the additional weight of the coating averaged 5,000 to 6,000 pounds, which caused some of the piles to sag in turning and handling, producing cracks in the coating.

It may be of interest to explain the methods of repairing the damaged cement coated piles under water. This was done by putting on a steel cylinder, about 6 inches larger in diameter than the coated pile, and around the part of the pile to be repaired. All joints were closed and the bottom of the cylinder was made to fit close to the surface of the pile, with the top of the cylinder open. On the deck, above the pile to be repaired, a tank was set up, with a large valve connected to a piece of 1½-inch single ply cotton hose, leading down to the bottom of the space between the pile and the cylinder. Cement grout was mixed in the tank and allowed to run down the hose, a diver keeping the lower end of the hose below the surface of the deposited cement until the top of the cylinder was reached. The cylinder was allowed to remain on for two or three days, then it was taken off and transferred to another pile to be repaired. The results were considered very satisfactory.

It is believed that if some method of rotating the pile, without sagging, during the application of the "gunite" can be devised, and also of handling the pile from the rollers to the seasoning yard, that this method can be satisfactorily, and, of course, economically, employed. It is undoubtedly less expensive than the solid concrete pile.

Mr. Carlin believes that a coating of about 1¼ inch would be very much bettem than 2½ inches, because it reduces the weight on the wooden-pile, and it sufficiently covers the reinforcement.

Germans Awarded Prize in Swedish Harbor Plan Competition

The first prize in the International competition for plans to enlarge its harbor was awarded by the city of Helsingborg, Sweden, to the firm of Ludwig Lange, Hanover, together with Marine-Hafenbaudirektor Behrendt, Wilhelmshaven, Germany. Albert Lilienberg and Lieut. N. A. Svenson, Gothenborg, Sweden, were awarded the second prize. The third prize went to Thuresson & Company, Stockholm, Sweden. The judges also recommended the purchase of the following, at $270 each: plans of Prof. R. W. Otto Schulze, assisted by Walter Rouff, Danzig, Germany; those by Ivar Tybjerg, Aalborg, Denmark, and those by Carl Semler and the Contractor Construction Company, Stockholm, Sweden. The harbor department itself decided to buy at the above mentioned figures the projects submitted by Lieutenant Plomann, Stockholm, and S. Ewald, city engineer of Helsingborg, assisted by the architectural firm of Lewerentz & Stubelius.

The time limit of the competition was set for July 15, 1914. The judges met for the first time August 1, 1914, but the work was interrupted the following day by the outbreak of the European war. It was not resumed until August 12, 1915, and it was completed August 24. Because of the unexpected length of time required before results were announced it was decided to increase the prizes and the sums of purchase to the extent of interest for one year at five per cent.

Million Acre-Feet Added to Reclamation Service Storage Capacity

More than 1,000,000 acre-feet were added to the capacity of its storage capacity by the U. S. Reclamation Service during the past year. Four large and interesting dams were brought practically to completion, namely: The Arrowrock, the highest in the world; the Elephant Butte, which impounds the largest quantity of water of any artificial reservoir in the world except Gatun Lake; the Grand River, which is the longest roller-crest dam in the United States, and the Lahontan. Water was furnished to irrigate more than 750,000 acres of land and to grow crops worth $16,500,000. The total expenditure during the year for building dams and other irrigation works was $15,000,000. Construction completed included 753 miles of canals, 284 miles of waste-water ditches and open drains, 60 miles of irrigation and drainage pipe lines, 747 bridges, 1,079 culverts, 311 flumes, 51 miles of roads and 178 miles of telephone lines. Irrigation canals were lined with concrete to a total length of 54 miles. The excavation of earth and rock amounted to 17,000,000 cu. yds. and 750,000 cu. yds. of concrete were placed.

Depressed Kiln Centres Save Ware and Bagwalls

"One idea has saved me thousands of dollars," said a New York brickmaker in discussing the subject of kiln construction.

"An item of no mean consideration in the maintenance cost of kilns comes from damaged bagwalls due to the brick rolling toward that part of the kiln. But what is of still greater importance is the amount of ware spoiled when this occurs. I have found that by depressing my kiln centres from one and one-half to two inches in a thirty-foot round, down-draft kiln, much of the trouble, expense and actual loss due to damaged bagwalls, and distorted and melted brick, is obviated. Where this is done, when the brick begin to roll, the tendency is to lean toward the centre of the kiln, thus keeping the setting intact.

"This simple idea has saved me a large sum of money in the time that I have made use of it, in repairs to bagwalls and in a smaller number of culls."

Tenders and For Sale Department

School Tenders

Sealed tenders will be received up to and including **Saturday, January 15, 1916,** by the Secretary of the School Board, Lambton Mills, in whole or in part, for the different trades required in the erection and completion of a school building. Plans and specifications and all particulars can be seen at Molson's Bank, Lambton Mills; also at the offices of the architects. No tender necessarily accepted. A guarantee bond for 10 per cent. will be required from the parties to whom the contract may be awarded.

THOMAS ELLIOT,
Secretary-Treasurer School Board,
Lambton Mills, Ont.

Ellis & Ellis, Architects,
Manning Chambers, Toronto. 51-1

The Quebec Streams Commission

Proposed Bridge on the River Sauvage at Lambton, County Frontenac, P. Q.

Notice to Contractors

Sealed tenders, addressed to the undersigned, and marked "Tenders for a bridge over the Sauvage River," will be received at the office of the Quebec Streams Commission, Room 125, Parliament Buildings, Quebec, until twelve o'clock on **Tuesday, the 11th day of January, 1916.**

These tenders shall be for the following items:

(A) Tender for a wooden bridge, wooden piers and abutments and bridge approaches.

(B) Tender for Concrete Piers and Abutments and Bridge approaches.

(C) Tender for Steel Superstructure of Bridge.

(D) Tender for Items B and C combined, viz.: Concrete Substructure and Steel Superstructure.

Any tenderer may submit prices for one or all of the above items.

Plans and specifications can be seen after this date in the office of the Chief Engineer of the Quebec Streams Commission, Room 803 McGill Building, Montreal.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor of the Province of Quebec, which schedule will form part of the contract.

Tenderers are notified that tenders will not be considered unless made strictly in accordance with the printed forms.

An accepted bank cheque for a sum as mentioned below made payable to the Hon. the Provincial Treasurer, must accompany each tender, which sum will be forfeited should the party tendering decline to enter contract for the work, at the rate stated in the offer submitted.

Item "A" cheque for $2,500.00.
Item "B" cheque for $4,000.00.
Item "C" cheque for $3,000.00.
Item "D" cheque for $7,000.00.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security for the due fulfilment of the contract to be entered into.

The lowest or any tender will not necessarily be accepted.

By Order,
L. H. CHARLEBOIS,
Secretary.

The Quebec Streams Commission,
Montreal, December 23rd, 1915.

Unauthorized publication of this advertisement will not be paid for. 52-1

Tenders for

STREET CARS

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon, on **Tuesday, February 1st, 1916,** for the supply and delivery of:—

	Tender Numbers
Street Cars, Complete	70
Street Car Bodies	70-A
Street Car Trucks	70-B
Street Car Motor Equipment	70-C
Street Car Air Brake Equipment	70-D
Copper Cables for Street Car Work	70-E
Street Car Fare Boxes	70-F

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of City By-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman, Board of Control.

Toronto, December 30th, 1915. 1

Sealed tenders, addressed to the undersigned, and endorsed "Tender for Temporary Postal Station 'A,' Toronto, Ont.," will be received at this office until 4 p.m. on **Monday, January 10, 1916,** for the construction of the building mentioned.

Plans, specification and form of contract can be seen and forms of tenders obtained at the office of Mr. Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, December 29, 1915

Newspapers will not be paid for this advertisement if they insert it without authority from the Department. 1

Concrete Mixers

Large company in Middle States making concrete mixers wants selling agents for Canadian territory. Good working arrangement and substantial assistance will be given to reliable aggressive agents. Box 279, Contract Record, Toronto, Ont. 1-4

Quarry Machinery Wanted

Two gang saws and one planer in good working order.

F. ROGERS & COMPANY,
1193 Queen Street West,
Toronto, Ont.

Late News Items

Avonbank, Ont.
Plans are being prepared for a residence to be erected for A. Ready. Red pressed brick construction, concrete foundation. Approximate cost, $3,500.

Frome, Ont.
Robert S. Chute has decided to erect a barn and other outbuildings to replace those recently destroyed by fire.

Maisonneuve, Que.
J. A. Coulcombe, 134 Stadacona Street, has commenced the erection of three flats on Pie IX. Street, estimated to cost $7,000. Some of the smaller trades will be let. Stone and brick construction, felt and gravel roofing.

Muirkirk, Ont.
The erection of a school is being considered by the School Board. Approximate cost, $5,000. Trustee, P. A. McKellar.

Niagara Falls Centre, Ont.
W. C. Pretty, 751 Ferry Street, will receive tenders until January 6th for all trades except plumbing required in the erection of a residence and garage on Ferry Street. The contract for plumbing has been awarded to Payne & Nesbitt, 122 Main Street.

Portage la Prairie, Man.
The Public School in the East Ward has been totally destroyed by fire. Loss, $30,000; insurance, $18,000. Chairman of the Public School Board, R. H. Home.

Quebec, Que.
Plans are being prepared for a bank building to be erected on Ste. Foye Road for the National Bank, 75 St. Peter Street. Architect, P. Levesque, 115 St. John Street. Brick construction, concrete foundation, metal roofing. Estimated cost, $5,000.

Renwick, Ont.
H. DeClereck is considering the erection of a residence to replace that recently destroyed by fire. Estimated cost, $3,000.

Sexsmith, Ont.
Robert Tinney, Sexsmith, Exeter, Ont., is preparing plans for remodelling his barns and the construction of stables beneath them.

Principal Contents

Better Design of Reinforced Concrete

WITH the increasing demand for reinforced concrete in all fields of structural endeavor the necessity for a fuller and more accurate knowledge of the stresses in beams and columns of different design is at once evident. Mr. M. T. Cantell covers in his paper on Reinforced Concrete the necessity for better designing in reinforcing to secure the greatest strength in concrete members and at the same time effect the strictest economy. The article, printed on other pages of this issue, briefly covers the merits of concrete as a compression member, steel as a tension member, and the benefits derived by effecting a combination of the two. Concrete has a crushing strength when a month old of upwards of 2,500 lbs. per square inch. This increases with age. In tension, however, its ultimate resistance is about 200 lbs. per square inch, while steel ranges from 60,000 to 100,000 lbs. per square inch, but diminishes with age due to oxidation by exposure to moisture, acids, and atmospheric conditions.

In reinforced concrete, properly designed and made, these two materials act together as one, with the advantages of both and the disadvantages of neither. Consequently, we have the strength, toughness, and rigidity of steel, the appearance of stability and strength, the steel permanently insulated from oxidation, no loss from age, a saving in the cost of construction, speedy erection, very little or no maintenance charge, and a material adaptable to all forms of architectural and structural work. Of the valuable properties of the work, few will exist if the work is not properly designed and executed. In designing, strength is considered the chief point. Strength, however, should be considered with economy. An economical structure would have a certain arrangement of beams, slabs, columns, etc., all spaced and proportioned in the most efficient manner, with a definite percentage of reinforcement, all determined with regard to the loading, with a view to obtaining the strongest, most satisfactory, and cheapest structure.

For economical structures the most important factors to consider are—the ratio of depth to breadth of beams, the percentage of reinforcement, and the general layout of beams and columns. For rectangular beams the most economical section is the ratio of 1 to 3 breadth to depth. The utmost attention should be paid to the percentage of reinforcement as great waste is often occasioned through an excess of steel being used. The fundamental principles underlying beam design should be carefully studied, the chief factor concerned being the neutral axis of the beam and what governs its position. Knowing this, it is only a simple mathematical problem to design a formula whereby we can determine the section of the beam that will contain sufficient concrete above the axis to take the compression, and the percentage of reinforcement necessary to develop the required stresses. The nature of the materials is a very important consideration. Portland cement of standard specifications, with mild steel reinforcement, should be used. Carbon steel should not be used, as its yield point is not so reliable as mild steel.

Sewage Disposal by Dilution

THE subject of Sewage Disposal by Dilution, on which much evidence has been collected by the British Royal Commission on Sewage Disposal, is most concisely stated and clearly described by Dr. W. E. Adeney in a paper before the Institute of Sanitary Engineers, England, which is printed elsewhere in this issue. It has been established in this Commission's investigations what amount of normal crude sewage—that is, liquid refuse containing organic matter in solution and suspension, and which is purifiable without previous treatment by living organisms—when discharged into a stream of known volume and velocity, under specified conditions, will not be detrimental to fish life or interfere with any other of the little amenities of the stream. Normal sewage discharged into a stream absorbs more or less rapidly the atmospheric oxygen dissolved in the water. This bio-chemical change between the dissolved oxygen and certain constituents of the sewage matter is brought about by two classes of water bacteria, one class feeding upon the waste organic constituents, and the other, a nitrifying bacteria, upon the ammoniacal constituents contained. The method of nutrition is very dissimilar to any other form of life, vegetable or animal. Water bacteria obtain the energy necessary to carry on their vital processes from oxidation of their own food rather than from the oxidation of any portion of their own substance. When amply supplied with dissolved oxygen they will convert upwards of ninety-five per cent. of the fermentable constituents of the sewage liquid in the polluted water into CO_2, nitrates, and humus, leave no product of their own action, and, when dead, constitute favorable food for green vegetable growths and other forms of life.

The quantity of dissolved oxygen available in the diluting water must be ample to fully oxidize the organic impurities in the sewage effluent and still leave sufficient to support fish life. When the sewage liquor discharged into a stream is in excess of what the dissolved oxygen in its waters will take care of, the bacteria flourish in such great numbers, owing to the surplus supply of food materials, that they absorb the dissolved oxygen more rapidly than it can be replenished by the absorption of fresh oxygen from the air, the result being that the water becomes de-oxygenated and is unable to support fish and other forms of life. The amount of sewage liquor which can be discharged into a stream therefore depends upon the quantity of oxygen dissolved in the waters of the stream, and it is plain that, if no ill-effects are to result, the dissolved oxygen in the mixed sewage liquor must be in excess of the amount necessary to combine with the fermentable constituents of the polluting liquid. Regarding the discharge of crude sewage, where the solids cannot easily be broken up and adequately supplied with dissolved oxygen during any fermentative changes exerted upon them by the water-bacteria, the stream must be of such a character that the solids can be transported and dispersed over large areas of clean bed; otherwise the solids deposit and become offensive.

Summed up, given a clean stream of sufficient volume and transporting power and a limited amount of pollution, the waters of the stream will become self-purifying, and no harm would result in non-potable waters.

Montreal Rejects Advice of C. S. C. E.

As predicted, the Montreal Council have rejected, by 22 to 7, the request of the Canadian Society of Civil Engineers that a board of independent engineers be appointed to report on the improvements to the city aqueduct, particularly the plans for a hydro-electric development for power and light. Alderman L. A. Lapointe, who favors the investigation, asked that a board of engineers submit a complete report and make such suggestions as they might deem advisable. He argued that power could be obtained from private companies at a smaller cost than under the civic scheme; in his opinion the cost of the scheme would be prohibitive. Controller Cote defended the plans on the ground that objections should have been taken in 1913 when the scheme was first authorized. He contended that the plans had been approved by competent engineers, with the exception of the large power house which would at a later date be laid before qualified engineers. The opposition came, he said, from electric companies, who might in the future form a trust and attempt to squeeze the city, and the city should therefore be prepared to do its own lighting. Mr. Cote claimed that the work should be proceeded with as soon as possible and if the Council adopted the report made by the Board of Control to arrange for the necessary loans, in the early spring the construction company would be in a position to start work again right away.

The council passed by-laws authorizing the raising of loans of $1,500,000, $680,000 and $500,000. The first loan will supply funds for the construction of the power house for the hydro-electric development, a wall for the enlarged aqueduct, two bridges, gates at the intake, etc.; the second loan is to continue the work of enlarging the aqueduct; and the third loan is for the cost of expropriations of land in connection with the proposed boulevards and streets on each side of the aqueduct.

With regard to Controller Cote's statement that the plans have been approved by competent engineers, it is the contention of the Council of the Canadian Society of Civil Engineers that while several engineers have reported on sections of the scheme, no outside engineers have reported on the complete scheme as it exists to-day, and that the original plans have been so altered as to make it imperative that a report on the whole project should be made by independent authorities. Further, it is certain the cost of the hydro-electric development will be very excessive, much higher than installations owned by private companies, while the citizens will also be burdened by an extravagant capital cost and by annual charges which make the generation of the 10,000 horse power an uneconomic proposition. The necessary power can be purchased at a smaller cost from the existing companies, and there is no justification for piling up expenditure on citizens already heavily taxed for much unproductive outlay.

Probable Life of Steel Bridges

The probable life of a steel bridge is a point of serious consideration, if this type of construction is to be generally used. The life of the steelwork will depend almost entirely upon the attention it receives from the maintenance forces. If properly painted with a good quality of paint there is no apparent reason why the life of a well designed steel bridge may not be very great. From observation of properly painted steelwork it is believed that under ordinary conditions our present riveted steel structure or I-beam spans should have a life equal to, if not greater than, much of our present concrete construction. To attain a life of even twenty years the steelwork must often receive attention, and corrosion must be checked before it seriously affects the metal. With the general tendency towards more efficient supervision of highway work we are able to provide greater assurance of prolonged life to our metal structures in the matter of keeping them properly painted and in repair. The elimination of details not easily accessible for painting, and the demand for more durable paints, have both tended to increase the general use of steel structures. The annual depreciation and maintenance charge need not be high if the steel receives the proper shop and field coats before erection, and if it is given the necessary attention after erection.—From a paper by J. H. Ames, Northwestern Road Congress, Cedar Rapids, Iowa.

New Deep Water Terminals at Halifax

Largest harbor work in progress in America 2,000 ft. of landing quay, six piers and berths — Unusual methods of quay wall construction

The Dominion of Canada, through its Department of Railways and Canals, is now engaged at Halifax, Nova Scotia, in the construction of one of the largest port developments in the world—a development which comprises not only an entirely new location of the ocean terminals of a port now over 150 years old, but also the radical revision of the railway entrance to the city. The scheme is of much more than local, or even provincial importance, inasmuch as it is part of the transcontinental railway enlargements fathered by the Dominion Government, and a bid for the transatlantic trade centering not only around interior Canada, but the great northwest section of the United States. Started in 1913, it has been consistently carried forward even during the financial stress of the past year, and has now reached a substantial advance in actual construction. Contracts already let total over $7,000,000. It is estimated that the finished scheme will cost four times that amount. The city of Halifax is located on the east coast of that peninsula, in a harbor of exceptional natural advantages. Direct passage is offered ocean steamers from the open sea through a wide bay entrance to deep-water berths protected from the force of wind and waves and faced by a basin of ample space for maneuvering. Although quite far north, it is ice-free the year round. Furthermore, it is the port in North America nearest to Europe. Its location on the continent is not so advantageous, inasmuch as while it is on the Nova Scotia peninsula, "the long wharf of Canada," all railway connections must go north to the neck of that peninsula to reach the mainland. It has, however, an old established railway which is tied up to the various Canadian transcontinental lines.

The city was founded in 1759 and had only a provincial importance until the beginning of the railway era, when for a time it promised to monopolize the trade of eastern Canada. The more orderly development of other Atlantic and St. Lawrence ports, and particularly their greater attention to trans-shipment and transportation necessities, soon caused them to surpass Halifax, and for many years it progressed but little as a port.

The defect at Halifax lay in poor railway connections, and more especially in inadequate and faultily located terminals. The main part of the city is situated on the east shore, about midway down a peninsula about five miles long and two miles broad, making out into the bay. This peninsula, particularly the northern section, rises rather abruptly from the shore, the rise continuing back to the neck. In consequence the early railway builders took advantage of the low level on the bay shore to bring the tracks to a point about half way down the shore line. Since the construction of the road, over fifty years ago, the city has grown southward, so that at present the centre of business is a long way from the terminals, and, more important, the shore south of the terminal has become crowded with private wharves, warehouses and factories, the removal of which to permit a southerly extension of the railway would be most costly.

For many years the ocean terminals have been in the congested districts just south of the railway passenger station, and in 1910, in an effort to improve conditions, the government undertook the reconstruction of this section, starting with the building of the large reinforced-concrete pier No. 2. It was felt, however, that such provisions were only makeshifts and that some radical revision of the whole harbor must be made if the port were to be developed to meet the national needs anticipated in the Canadian transcontinental and trans-oceanic trade expansion consequent on the rapid development of this vast country. To provide for this expansion the Intercolonial Railway has been greatly improved and will be double-tracked with revised grades from Moncton to Halifax.

The Intercolonial Railway now entering Halifax and its connecting line, the National Transcontinental Railway, both of which are under government control, form a continuous line from Halifax to Winnipeg under one management. At the same time the privately-owned railways of Canada are being extended with vigor. It has therefore naturally become a part of the Dominion's economic policy to develop an entirely Canadian control of the expanding trade between its people and Europe and to supplant the present partial control of existing trade by United States railways and

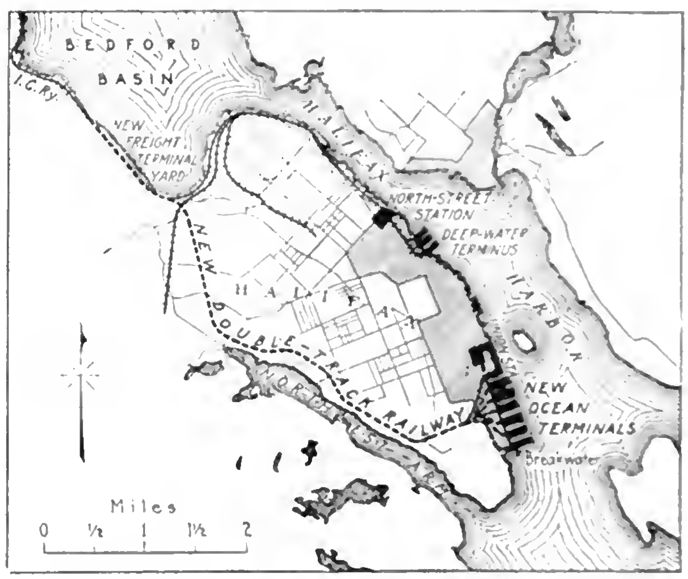

Fig. 1.—Map showing New Ocean Terminals at Halifax, N.S.

ports, dictated entirely by present superior economic advantages.

Halifax seems to have at least three dominant advantages to further this policy. It is the nearest port to Europe open all the year round and at all times, and should therefore be most desirable for transatlantic mail and passenger routes. It is a safe and easily accessible summer and winter port for Canada, thereby differing from the St. Lawrence cities. It is an all-year port of call for shipping between Europe and North America. The last-cited circumstance is considered a most important factor, as it promises to guarantee a sure and constant outlet to trade even though the port is not established as a terminal. The accepted path of transoceanic steamers bound for

* Engineering News.

United States ports would be lengthened only from twenty to fifty miles in calling at Halifax.

As a result of these considerations the government in 1912 decided to establish at Halifax a new deep-water terminal which should furnish safe and accessible landing facilities for vessels of the largest and most modern type and communicating railway terminals for passengers and freight located in the most desirable situation with regard to city population and industries.

An extended study of the harbor was made and designs were outlined at four different places—two makes its new detour back of the city, is to be built a large freight yard. A depth of 45 feet of water is to be provided at all berths except two which will have 30 and 35 feet respectively.

The whole project, from freight yard to terminal, is in territory not now in commercial use, so that business can be transferred from the old to the new location without interference or delay. At present only the railway connection, the landing quay, Pier A and the breakwater are under construction. In immediate prospect, however, is the erection of an elaborate terminal building which will house under one roof the re-

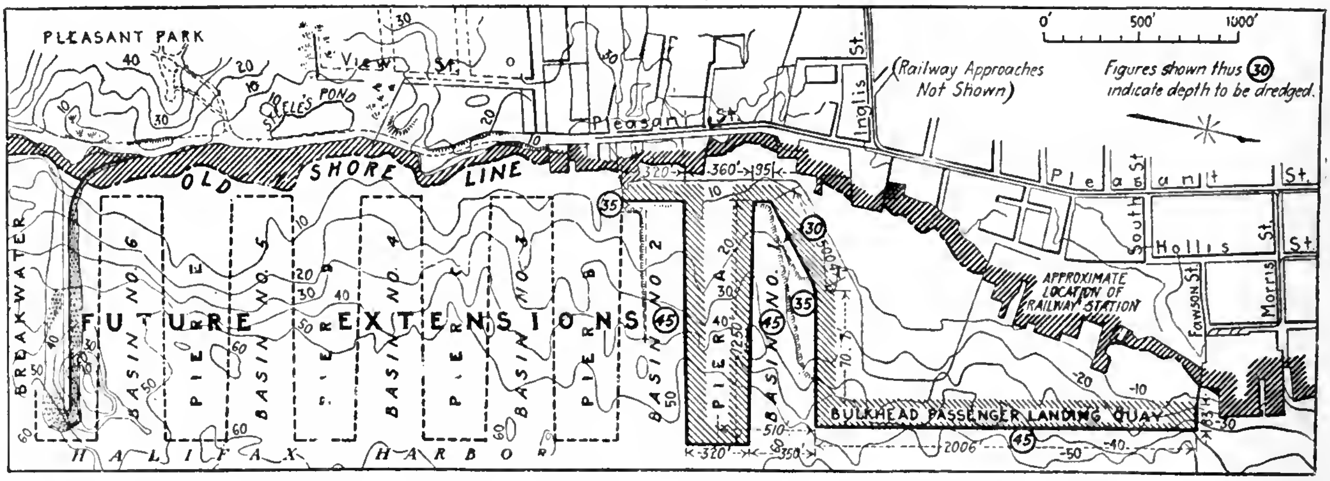

Fig. 2.—Halifax Ocean Terminals—showing Layout of Quay and Piers and location of Railway Station.

at Dartmouth on the opposite side of the bay, one an extension of the old terminals near the station, and one, which was adopted, near the south end of the peninsula. The Dartmouth schemes across the bay from Halifax were abandoned mainly because of the isolation of the sites, it being assumed from previous experience at other ports that it is difficult to establish new terminals removed from existing business centres. The extension of the present terminals was rejected largely because of the poor approaches along the narrow shore level and the expensive dislocation of the business district which would be required. The southerly plan was adopted because it did not have the disadvantages noted in the foregoing, and in addition, had several decided advantages, which can be enumerated as follows:

(1) A location convenient to the centre of the city; (2) utilization of a part of the city waterfront hitherto little developed, and largely unoccupied; (3) comparatively small effect on assessment value and taxation; (4) turning space in front of the terminals sufficiently large to permit the maneuvering of the largest ships; (5) convenience of the topography for a railway-terminal location; (6) sufficient depth of water to care for any ship now in existence or in contemplation; (7) room for a large freight yard; (8) possibility of extension at small cost.

The location of the new deep-water terminal is shown in Fig. 1 and the layout in Fig. 2. It consists of a landing quay 2,006 feet long and six piers with six berthing basins, all physically connected with a passenger and freight terminal approached by a double-track railway, which enters the city across the neck of the peninsula and connects with the piers through the point at the south end of the city. At the piers full equipment is to be provided in the way of warehouses, elevators and railway-terminal facilities, while on the shore of Bedford Basin, just before the railway quired facilities for steamship and railway-passenger service.

The total area to be used for the terminal will be about 260½ acres, of which 198½ will be land and 62 in water. The bulkhead landing quay, as stated, is 2,006 feet long, will have a minimum of 45 feet of water alongside and will carry for its full length a passenger and freight building, the ground floor of which is to be used for freight and the second floor for passengers, baggage, mail and express, connecting through a large concourse to the new Union passenger station for all the railways. On the north side of Basin No. 1 are berths for two ships, one 700 feet long, with a minimum depth of 35 feet of water, and the other 500 feet long with 30 feet of water, and each provided with double-storey freight sheds 100 feet wide, with three tracks at the back and one along the front of the quay. The five piers and basins, which have not as yet been started, will each be 1,250 feet long and each from 320 to 360 feet wide. The basins will be dredged to give a minimum depth of 45 feet at low-water level. There will be four berths to each pier and each berth will be provided with two-storey sheds and ample track connections. The layout of the station and terminal tracks is not yet complete.

At the extreme southern, or seaward, side of the piers a paved rubble-mound breakwater is being built along with the first unit of the docks. The breakwater will extend eastward from the shore into the harbor for a distance of about 1,500 feet, and will be built out to and upon an isolated ledge of rock which is at present in places very close to the surface of the water. When required by demands of business, a quay wall can be built along the inner side of the breakwater, which will itself then compose the centering for a new pier.

The landing quay and the piers are to be of earth and rock fill behind concrete walls of novel construction. The design was selected after careful study of the requirements, which may be outlined as follows:

(1) The great depth of water (45 ft.) to be provided at low water; (2) the varying levels of the present bottom of the harbor, particularly of the rock surface; (3) the dip in the strata and the irregular nature of the rock and its broken and laminated character; (4) the impracticability of cofferdamming on account of the exposure, great depth of water and danger of leakage through the rock; (5) the effect of the frequent ground swell and wind and waves on any staging and floating plants, difficulty in securing good bottom for piles and anchors, great length of spuds required for dredging with scows and the regulation of the plant to the rise and fall of the tide; (6) the low range of the tide and consequent difficulty in securing bracing for either temporary or permanent works; (7) necessity for practically a vertical-face wall on a wharf to suit the modern midship section; (8) necessity for protecting the face of the walls against disintegration from frost or sea water and the action of ships; (9) avoidance of taking out any more rock from under water than is absolutely necessary and having to replace it with concrete; (10) reduction of diver and expensive subaqueous work to a minimum; (11) necessity for rapid construction.

Quay-Wall and Pier Construction

The quay-wall method of construction consists in placing on a prepared bottom, in 30 to 60 feet of water, stacks of hollow reinforced-concrete blocks fitting one on top of the other to form the required height and joined together laterally to form the continuous wall. After setting these blocks, their cells, which line up vertically, are to be completely filled with concrete for the first 5 feet and above that each stack is to have its face cells and the middle line of transverse cells filled with concrete, the remainder of the other cells to be filled with stone rip-rap and sand so that in effect the completed wall will be a retaining wall with a concrete base and a concrete face strengthened with solid counterforts. Topping the wall above low water will be a granite-faced wall in the intertidal space and up to and including the coping, as a protection against the frost and sea-water action which might damage the concrete. The shed and warehouse structure will have their forward columns supported directly on the wall and their rear columns on pedestals footing on concrete-pile clusters driven through the fill which will be placed after the wall is completed.

The advantages of this method are that all the concrete is mixed with fresh water, molded in air, and allowed thoroughly to mature before coming in contact with sea water and placed so that it will not be subject to frost action. The mass concrete that is deposited under water is placed under conditions as nearly ideal as possible. The design of the walls obviates the necessity of using expensive temporary staging or floating cranes. Expensive foundations for the front row of the shed column are unnecessary. Settlement, expansion and contraction are provided for by means of the short sections and the leeway afforded by the reinforced-concrete guides.

While cellular concrete blocks for subaqueous wall construction are not new, in no other work have they been developed to such magnitude as at Halifax, nor has the method of placing and filling them ever been used before. At the present over 1,100 out of the 3,634 blocks required have been cast and are in storage at the site (see Fig. 5), but the placing has only just started, the first block being swung into place on September 25. The method in which the blocks are intended to be laid—which in the limited practice so far offered has proved very successful—can be outlined. The process of laying is also sketched in Fig. 4.

Placing the Concrete Blocks in Wall

The details of a typical block are given in Fig. 3. As shown in the general elevation, this block is only typical of those in the main part of the shaft, there being special shapes and sizes for the base blocks and for the top blocks. The block shown, however, is sufficiently typical for the purposes of description. It is 31 feet wide, the width of the completed wall; 4 ft. high and 22 ft. long, and weighs 60 tons. It is reinforced not only against its loads as a part of the wall, but against handling stresses. The walls are solid except for the triangular openings shown, provided so as to insure a good bond with the fluid concrete placed in the cells, and also vertical circular

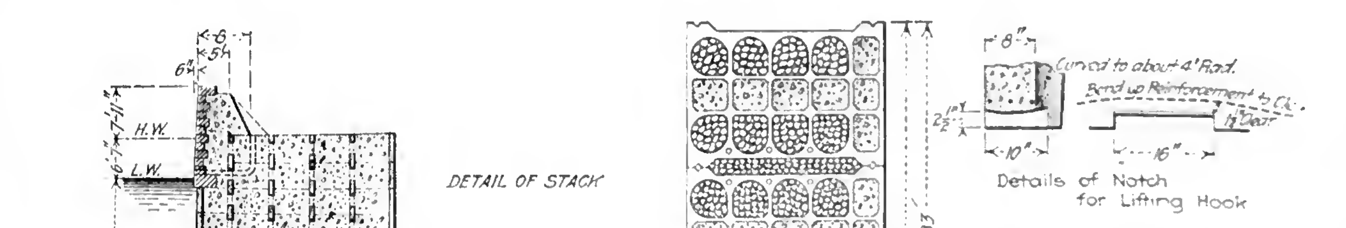

Fig. 3.—Details of the Concrete-Block Quay Wall 60-ton concrete blocks stacked up to form a 60 ft. wall.

openings for grouting, as afterward described. On each side are provided triangular vertical openings which serve as grooves to engage the square guide posts used in setting the blocks. These posts are in appearance the same as reinforced-concrete piles, and are cast in a similar manner. Great care is taken in getting plane surfaces and truly right-angled edges in the blocks, for upon these features depends the verticality of the finished wall.

The surface of the bottom, upon which the lowest block is laid, is prepared by dredging, or where already low, by filling up to the required grade with mass concrete or a rubble mound. The final levelling is made in the chamber of a diving bell. Inside of this bell the subsurface is cleaned up and where necessary at the back or front brought to proper elevation by filling holes or depressions with concrete, and then low concrete pedestals each about 5 x 6 ft. footing on solid rock, or concrete or rubble fill, are laid, with tops finished to true grade about 3 inches above the surrounding bottom. These pedestals are located at back and front at the junctions of stacks of blocks. The first block is then picked up with special tongs slung from a travelling crane, the jaws of the tongs fitting into specially prepared openings in the bottom of the block. With the crane running on a standard gauge track and standing with outriggers set on an already completed stack (see Fig. 4), the block is lowered overboard, effort being made to keep it lightly engaged against the vertical guide posts which have been plumbed and fastened into the corresponding grooves in the last stack already set. After the block is lowered to bearing on the pedestal, the succeeding blocks of the stack are placed until the stack is complete. The sealing concrete for the two bottom risers is then placed by bottom-dump buckets from a floating concrete mixer or delivered from the molding yard concrete mixer by flat cars running on the standard gauge track behind the crane, and then the filling of the proper cells with concrete to the top of the stack is completed. After this filling is finished, grout is forced into the vertical 10-in. holes, which,

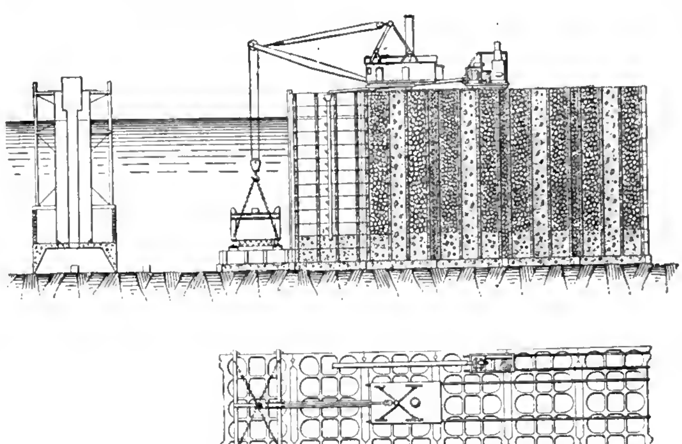

Fig. 4.—Method of laying blocks in the quay wall—Halifax Terminals.

matching up, form a continuous well through the stack. It is expected that this grouting will fill any voids left where the bearing of the blocks is not perfect or the concrete filling has left holes. Finally, the remaining cells are filled with rubble gravel and sand.

The placing of the blocks has from the first been attended with the greatest success. The guide and key posts which are carefully plumbed for each stack automatically bring the blocks into true position without the assistance of a diver whose services are required only for inspection and to see that all is clean and clear for the bottom blocks and mass concrete of each stack. No difficulty is found in keeping the stacks vertical or in securing good alignment. The tendency to "creep" longitudinally or to get out of line is corrected by using different combinations of the three standard sizes of posts provided. The variation in levels between the highest and lowest corners of the top blocks of the stacks as set does not

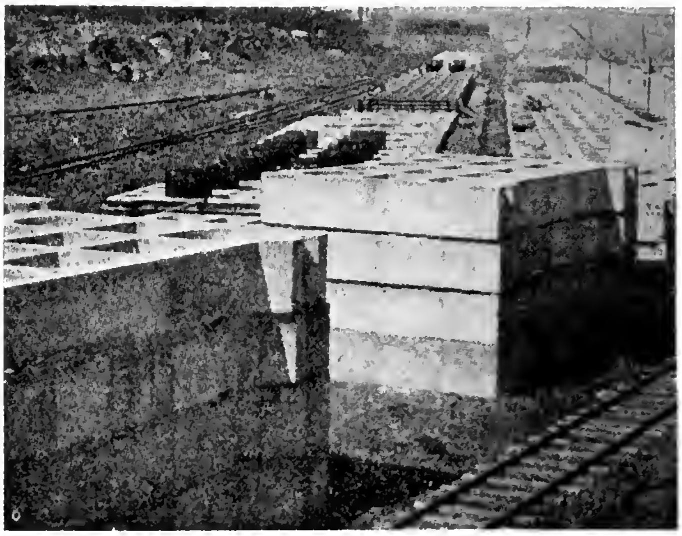

Fig. 5.—Hollow Concrete quay blocks in storage at Halifax.

average more than one-half inch. Blocks for about 500 feet of wall have already been set with a 150-ton standard-gauge steam locomotive wrecking crane which travels out on ordinary railway track laid on stringers resting on the stacks of empty blocks and extended by stack lengths of 22 feet as the block setting proceeds. The same crane is used for lifting the blocks from the molding platforms to standard flat cars on which the blocks are transported out to the wall head. As many as two stacks each of nine blocks have been set in one working day and an average per day of one stack of blocks loaded from the yard and set in the wall is easily maintained.

As the map in Fig. 1 shows, the new railway entrance leaves the old main line at the lower end of Bedford Basin and continues down the west side of the city to the terminals, a distance of about six miles. Except for the freight yard along the shore of the Basin and the four-track approach to the terminal yards, the line will be two-track. On account of the topography and the short length of the new line, it was impossible to balance the cuts and fills, so most of the work is in cut, the spoil being carried north to make the freight yard and south to the breakwater and back fill of the quay and pier walls. The total excavation is about 1¾ million cubic yards and the deepest cut about 60 feet.

Some difficulty was experienced in locating the line because the Northwest Arm, along which it runs, is a beautifully wooded section highly desirable as a residential, park and recreation district. On this account the line was kept well back from the water, and all crossings of streets leading to the water side district are to be carried above grade on handsome reinforced concrete arch bridges.

The landing quay and piers were located to fit as

(Continued on page 40.)

Mineral Productions of Canada, 1914

Some interesting figures covering mining, reduction and refining—Exports and imports—Coal still ranks highest in Value

The Department of Mines, Ottawa—Eugene Haanel, Director—have just issued three advanced chapters of the Annual Report on the Mineral Production of Canada during the calendar year 1914. The table herewith is a short summary of the production, exports, and imports of the various minerals. By "production" is meant the tonnage actually sold as used apart from the term "output" as applied to that total supplied at the mine, which includes loss due to unsaleable material, or stock on hand at the end of the year.

Pig-Iron and Steel

The iron and steel industry in Canada in 1914 was marked by a general decrease in production. The war in August caused an almost immediate collapse of the declining industry. Before the close of the year, however, the demand for steel for munitions and war supplies enabled many of the steel companies to resume operations on a large scale. At the beginning of the present year (1916) the steel industries are actually booming.

The making of iron and steel in Canada is an industry which has been built up largely on the basis of imported ores. The output has increased very rapidly from 1909 to 1913, but through the lack of demand fell off very considerably in 1914. At the close of that year Canada had twenty-two completed blast furnaces, grouped in twelve separate completed plants owned by nine companies or corporations. Eleven of these were idle during the year 1914.

The classification of the coke iron produced in 1914, according to the purpose for which it was intended, was—Bessemer, 230,817 tons; basic, 614,845 tons; foundry, including miscellaneous, 224,741 tons. Previous to 1896 pig-iron was made entirely from Canadian ores. Since that date, however, increasing quantities of imported ore have been used as well as imported fuels and fluxes, and in 1914 about 88 per cent. of the ore charged, 64 per cent. of the coke, and a large proportion of the limestone, were imported. The imported ores used in Canadian furnaces came chiefly from Newfoundland and the iron ranges south of Lake Superior.

Ferro Products

Ferro-silicon and ferro-phosphorus products were produced in Canada in electric smelting plants during 1914, the latter in small quantities only. Ferro-silicon, both 50 and 75 per cent., were made at Welland, Ont., by the Electro-Metals, Limited, and ferro-phosphorus, or phosphate of iron, at Buckingham, Que., by the Electric Reduction Company, Limited.

Steel was produced in 1914 in the following proportions: open hearth ingots, 622,097 tons; Bessemer ingots, 175,244 tons; direct open hearth castings, 15,315 tons; and other steel castings, 1,759 tons. The production of rolled iron and steel amounted to—rails, 382,344 tons; structural shapes and wire rods, 59,050 tons; plates, sheets and bars, 218,125 tons. Since 1896 a total of $16,785,827 has been paid by the government of Canada in bounties for the production of iron and steel.

The exports of iron and steel from Canada consist chiefly of manufactured goods such as agricultural implements, automobiles, bicycles, machinery, etc., and amounted to $14,391,746, in 1914. The imports of iron and steel, a large proportion of which come from the United States, consist mainly of pig-iron, Ferro products and chrome steel ingots, scrap, plates, sheets, bars, rods, sheet-iron and steel, pipes, nails, wire, etc., to the amount of $79,762,262, in 1914.

Coal

The coal production in 1914 was 13,637,529 tons, produced by 221 operating companies, employing an average of 27,571 men. The total consumption of coal in 1914 in Canada amounted to 26,852,323 tons, or 3,325 tons per capita. Almost all kinds of coal are produced in Canada. Bituminous coal constitutes by far the largest proportion of the annual production. Lignite only is produced in Saskatchewan, and in Alberta it forms a large proportion of that province's production. Of anthracite there is an almost negligible amount—less than 200,000 tons annually from one mine at Bankhead, Alberta.

Nova Scotia produces 54.77 per cent. of the Canadian coal, with Alberta next with 27.01 per cent., B. B. 16.42 per cent., Saskatchewan, 1.70 per cent., and Yukon 0.10 per cent.

The fact that the populous provinces of Quebec and Ontario have no coal-fields, and can secure most of their required amount more cheaply from the coal-fields of Pennsylvania, Ohio, and Virginia than from the Canadian coal-fields, accounts for Canadian imports exceedings 50 per cent. of Canada's annual consumption.

Coke

Both domestic and imported coal is used in the manufacture of coke in Canadian coke-ovens. In 1914 1,038,235 tons of domestic coal and 503,312 tons of imported coal were used to produce an output of 1,015,253 tons of coke. The Canadian consumption of coke in 1914 was 1,509,068 tons; 553,046 tons were imported during that year.

For the first time in history, Ontario leads in coke production with 386,314 tons, all of which was produced by the Algoma Steel Corporation. The coke exports for 1914 were 67,838 tons, all from British Columbia. In 1914 the total coke-oven by-products recovered at Sydney were—5,714,172 gallons of tar, 8,577 tons of sulphate of ammonia.

Aluminium

No commercial ores of aluminium have yet been found in Canada. Aluminium is, however, made in extensive works at Shawinigan Falls, P. Q., from bauxite ores imported from France and the United States by the Northern Aluminum Company. Alumina is imported, refined and exported as aluminium.

Antimony

The silver-cobalt-nickel-arsecnides of Coleman and adjacent townships, more familiarly known as the Cobalt District, in the province of Ontario, are now the principal sources of the world's production of cobalt. The recovery of this metal in Canada has been in the form of cobalt oxide and mixed oxides of cobalt and nickel, produced by the smelters treating the above ores together with cobalt residues produced at the high-grade mill of the Nipissing Mining Company. While these residues have been chiefly exported, a portion has been shipped to the Canadian smelters producing cobalt oxide. Bounties amounting to $26,744.75 on cobalt oxide, and $10,280.28 on nickel oxide, were paid to the Canadian refineries in 1914.

Copper

The total production of copper in Canada in 1914, estimated on the basis of smelter recovery from ores treated, was 75,735,960 lbs With the exception of a small output of copper sulphate at Trail, B. C., the copper production of Canada is exported for refining. In 1914 British Columbia led in copper production with 41,219,202 lbs., Ontario second with 28,948,211 lbs., Quebec 4,201,497, Yukon 1,367,050. In British Columbia the principal producers were—Granby Consolidated Mining and Smelting Power, Limited; B. C. Copper Company, Limited; and the New Dominion Copper Company, Limited. In Ontario the chief companies are the Canadian Copper, Limited, and the Mond Nickel Company, Limited. The Ontario Government offers a bounty on copper over 95 per cent. pure metal, and on copper sulphate produced from ore mined and refined in the province. The main shipments of copper from the Yukon were from the Pueblo mines at White Horse.

Gold

The production of gold was made up in 1914 as follows—gold derived from alluvial workings, $5,687,-501, or 35.6 per cent.; gold obtained from crushing free milling quartz ores—that is, stamped mill bullion, $6,-051,968, or 37.9 per cent.; and gold obtained from ores and concentrates sent to the copper and lead smelters, $4,243,538, or 26.5 per cent.

Refined Metal—The Dominion Assay Office in Vancouver, operated in connection with this Department, receives, assays and purchases crude bullion, amalgam, nuggets, and dust, the resultant bullion being re-sold. The total quantity of bullion thus received during the twelve months ending December 31, 1914 was 163,523.61 ounces, being the weight after melting, valued at $2,029,251.31, after deducting office charges.

A refinery is in operation at the Royal Mint at Ottawa and shipments of gold have been received from various provinces.

There is but one other refinery in Canada producing fine gold; that of the Consolidated Mining and Smelting Co. of Canada, Limited, at Trail, B. C., where the gold is mainly recovered from the high grade silver-lead ores and the "dry" ores shipped to the smelter. Its annual output is given below.

Lead

Previous to 1904 lead ores mined in Canada were either exported as ore or smelted in Canadian furnaces and exported in the form of base bullion to be refined abroad. A lead refinery employing the Betts electrolytic process is in operation at Trail, B. C., at the smelter there, treating the base bullion produced by the lead blast furnaces. The production of lead has been mainly from British Columbia, with occasional small amounts from Ontario. In 1914 there were no shipments from Ontario, but a small production in the Yukon. Almost all of the lead ore mined in British Columbia is smelted and refined at Trail, B.C.

Mercury

There has been no production of mercury since 1897. The small production reported in 1895 and 1897 was derived from the deposits at the western end of Kamloops lake, B. C. These deposits consist of quartz veins containing pockets of cinnabar in a zone of decomposed Tertiary volcanic rocks.

Elsewhere in Canada mercury has been reported as occurring also in ores of the Cobalt district, and in the neighborhood of Field, B. C., and Sechart on the west coast of Vancouver island.

Molybdenum

The commercial production of molybdenum in Canada has been practically negligible, nevertheless the mineral has been found in numerous localities and in many of these in sufficient quantity to make its possible recovery a question of considerable interest, an interest which doubtless has been greatly stimulated by the high price which the ore, concentrated to 85 or 90 per cent. molybdenite (MoS_2), has commanded.

During 1913 and 1914 some work was done on a number of properties in Ontario, Quebec, and British Columbia.

Shipments were made during 1914 from Ontario and British Columbia. The Ontario shipments consisted of one-half ton of molybdenite hand picked from the ore, while from British Columbia 16 tons of ore were reported as shipped to Denver, Col., where it was concentrated, producing 2,814 pounds of concentrates for which 20 cents a pound was received. The total shipments in the form of molybdenite were 3,814 pounds valued at $2,063.

Nickel

The industry based on the mining and metallurgical treatment of the nickel-copper ores of the Sudbury district, Ontario, ranks among the most important of Canada. Not only is there a considerable production of copper but the nickel, which is the most important product, supplies a very large proportion of the world's consumption of the metal.

The production of nickel ore, very active during the first six months of 1914, was checked on the declaration of war. Towards the end of the year the output was greatly increased, due no doubt to the great demand for nickel for war supplies, so that the production in 1914 was but little less than that of 1913, when the production of ore and its reduction to a Bessemer matte was the highest on record.

There were mined in 1914, 1,000,364 tons of ore, and smelted 947,053 tons; from which were produced 46,396 tons of Bessemer matte, carrying approximately 22,759 tons of nickel and 14,448 tons of copper, the net value of the matte being $7,187,031. Thus, in 1914, the matte showed an increase in copper content and a falling off in nickel due to the great increase in production of ores by the Mond Nickel Co., and their reduction in the Coniston Smelter and the curtailment of the Canadian Copper Company's output of ores which are relatively lower in copper content.

The nickel-copper ore is reduced in smelters and converters to a Bessemer matte containing from 77 to 82 per cent. of the combined metals, having averaged for the past year 49.0 per cent. nickel and 31.1 per cent copper, against 52.7 per cent. nickel and 27.4 per cent. copper in 1913.

The companies engaged in mining and smelting nickel ores are: The Canadian Copper Company, subsidiary to the International Nickel Company, with smelter at Copper Cliff, Ontario, and refinery at Bayonne, New Jersey; the Mond Nickel Company, Conis-

(c) Ore exported for refining.

Summarized Table showing Production of Canadian Ores, Exports and Imports in Minerals during the calendar year, 1914.

ton, of London, England, with smelter at Coniston, Ont., and refinery at Clydach, Swansea, Wales. The British America Nickel Corporation continued development work. The Alexo mine, on the Porcupine Branch of the Timiskaming and Northern Ontario Railway, was again a producer, shipping nickel-copper ore to the Mond smelter at Coniston.

Platinum

In past years the chief source of the platinum production of Canada was the placer gravels of British Columbia, principally in the Similkameen district. During 1913 operators in the Cariboo district of British Columbia report a recovery of 18 crude ounces of platinum valued at $489. More attention is being paid to the recovery of this metal especially in the Similkameen where it is proposed to re-work some of the old placers.

One or two companies operating in the Quesnel River district report small quantities of platinum with placer gold but the information is not sufficiently definite for record.

Silver

In 1914 the total production of silver, including that produced as bullion, and the metal estimated as recovered from ores sent to smelters or otherwise treated, was 28,449,821 fine ounces, valued at $15,593,630.

In Ontario ores from the Cobalt district are treated by:—The Coniagas Reduction Co., Thorold, Ont.; The Deloro Mining and Reduction Co., Deloro, Ont.; The Buffalo and Ontario Smelting and Refining Co., Kingston, Ont.; Dominion Refineries, Limited, North Bay, Ont.; Standard Smelting and Refining Co., North Bay, Ont.; Metals Chemical Co., Welland, Ont.; Canada Refining and Smelting Co., Orillia, Ont.

Silver bullion of a fineness varying from 850 to 998.2 is produced at the works, other products being white arsenic, nickel and cobalt-oxides and mixed oxides. The silver bullion as a rule finds a market in the United States and in England. The bullion shipped from the mines and mills in the Cobalt district in 1914, is reported as 10,335,527 fine ounces. The imports of silver bullion into Canada in 1914 were valued at $629,279, as against imports to the value of $840,245 in 1913 and $1,100,344 in 1912. The exports of silver during 1914 were 28,020,089 fine ounces valued at $15,584,813.

Tin

Tin ores have not yet been found in sufficient quantities in Canada to be of economic importance.

Tungsten

No production of Tungsten reported during 1914.

Zinc

The production of zinc in Canada in 1914, as obtained by direct returns from producers, was 10,893 tons, valued at $262,563, the greater part being from British Columbia. The zinc content of these shipments was returned as 9,101,460 pounds, which, if valued at the average New York price of spelter during the year, 5.213 cents, would be worth $474,459.

Road-Making with India-Rubber

The use of India-rubber for road manufacture is reported by Sanitary Record and Municipal Engineering. Recently a firm of tar distillers in England got in touch with an India-rubber manufacturer with a view to producing a material which would combine all the properties of India-rubber with those of tar. After this rubber tar, as it is called, had been made for road-making and road-dressing purposes it was found that its high viscosity and melting point caused its application to roads too difficult. This has been overcome by the construction of special tanks to keep the rubber tar hot.

The advantages claimed for this type of road construction are the elasticity necessary to withstand the shocks from heavy vehicles, homogeneity and adhesion required to avoid disintegration by fast running vehicles. A length of road has been laid in Fife with this material, and although put down at an unfavorable time, is so far giving satisfaction, and further developments with it are being carefully watched by experts.

The Disposal of Sewage by Dilution

A bio-chemical method of purification—Effect of normal sewage on streams—Much depends on amount of oxygen dissolved in water

By W. E. Adeney D. Sc., F. I. C.*

A large volume of evidence has been accumulated of recent years by the Royal Commission on Sewage Disposal, and by a number of individual investigators, both at home and abroad, which has definitely proved that, when normal crude sewage matter is discharged into a non-tidal or tidal stream, under such conditions that the liquid portion is rapidly and largely diluted with "clean" water, and the solids in suspension are carried away with the flow of the stream, and are not allowed to accumulate permanently in any particular spot, both portions of sewage matter are consumed as food materials by various forms of living organisms, and converted into innocuous forms of matter, without causing at any time injury or detriment to the fish life or to the amenities of the stream.

Notwithstanding this evidence, however, much doubt and uncertainty still appears to exist among engineers and chemists as regards the precise conditions which must attend the discharge of sewage matter into a given stream to ensure the satisfactory disposal of the sewage matter, and to avoid undesirable results of any kind in the stream itself.

It may be fairly claimed that the chemical and biological principles which underlie the dilution method of purification have now been successfully worked out; and the writer proposes to give in the first place a brief explanation of them. They are fortunately very simple, and the experienced water engineer need have no hesitation in proceeding to tackle them.

Absorption of Dissolved Oxygen

Some years ago the writer concluded from the results that he had obtained from an extended experimental investigation that the most important effect that normal sewage matter exercises in a stream is the more or less rapid absorption of the atmospheric oxygen dissolved in the waters of the stream.

This conclusion has since been confirmed by the laborious and prolonged investigations that have been carried out by Dr. Houston, Dr. McGowan, Mr. Colin Frye, and Mr. Kershaw for the Royal Commission on Sewage Disposal; by the extensive series of observations carried out by Dr. Soper, president of the Metropolitan Sewerage Commission of New York, and by his assistant, in New York Harbour; and by the observations of other investigators, both at home and abroad, and notably in this country by Prof. Letts and his pupils in Belfast, and by Dr. Fowler and his pupils in Manchester.

The absorption of the dissolved oxygen is caused by bio-chemical changes which water bacteria, by reason of their quite unusual mode of nutrition, bring about between the dissolved oxygen and certain of the constituents of the sewage matter.

Two classes of bacteria take part in these changes. First, the saprophytic (Greek word sapros=rotten) bacteria feed upon the waste organic constituents of the sewage matter; and, secondly, after the organic constituents have been wholly consumed, the nitrifying bacteria feed upon the ammoniacal compounds.

*Before the Institute of Sanitary Engineers, England

Both these classes of bacteria flourish in the open—in fresh and in sea water; and they are therefore unlike in this particular the disease-producing bacteria, which are always parasitic and cannot live in open water.

The chemical changes which these bacteria effect in polluted waters may be conveniently termed fermentative or bio-chemical changes, to distinguish them from those purely chemical changes which occur between bodies that exhibit direct chemical affinity for one another when they become mixed together.

Practice of the Dilution Method

Saprophytic bacteria can utilise the dissolved and solid suspended organic constituent of sewage matter as food materials, but in the practice of the dilution method, for reasons which will become plain later on, it must be the aim of the engineer to allow as little opportunity as possible for the solid constituents of sewage matter to be attacked by the water bacteria. The physical conditions of the stream must be such as to ensure their consumption by living organisms higher in the scale of life than bacteria if they are to be discharged into it. Otherwise they must not be allowed in the stream.

It is necessary therefore to consider the question of the disposal of the liquid portion of sewage matter separately from that of the disposal of the solid portions, and it will be convenient to deal with it first.

It is possible by suitable experiments to trace the chemical changes that occur in a diluted sewage liquor, simultaneously with the absorption of dissolved oxygen in the diluting water, and it has been found that in all cases where the dissolved oxygen is in excess of the sewage liquor the chemical decomposition of the latter takes place in two quite distinct and progressive stages of chemical change.

During the first stage, as already indicated, the organic constituents are alone affected—about 80 per cent. of them are completely oxidised to carbon dioxide, water and ammonia, the remaining 20 per cent. being utilised by the bacteria in building up the new materials that they require for their growth and multiplication. But, inasmuch as these building up, or, as the chemist terms them, these synthetic processes, are exercised upon organic materials of complicated composition, it will readily be understood that by-products must also result from them.

These by-products are coloured organic substances, remaining in solution, or rather in a colloidal condition in fresh water, and imparting a greenish yellow to brown tint to the water, according to the quantity of sewage liquor originally mixed with it. They are precisely similar in their physical and chemical properties to the "humus" of cultivated soils.

In the case of sea water, however, these humus bodies do not remain in solution, or suspended in it in a colloidal state, but are precipitated from it more or less rapidly as they are formed.

Thus, by the action of saprophytic bacteria upon the dissolved organic constituents of the sewage liquor, when amply supplied with dissolved oxygen, about 80 per cent. are completely oxidised to the min eral forms of matter—carbon dioxide, water and ammonia; and of the remainder, much the greater part—upwards of 15 per cent—are converted into "humus," also a mineralised form of matter; while less than 5 per cent. go to form the substances of the new bacteria.

After the bio-chemical destruction of the organic constituents of the sewage liquor has been accomplished, the second stage of change is started, and in the course of time completed by the nitrifying bacteria. These bacteria feed upon the ammoniacal compounds originally present in the sewage matter, and also upon those formed during the first stage of fermentation. The "humus" matters, also formed during the first stage of fermentation, likewise exercise a very important influence on the course of fermentation of the ammoniacal compounds.

Thus, when they are absent from a water or present only in minute quantities, as in the case of sea water, relatively large quantities of nitrites, but little or no nitrates, are found among the end products of the fermentation; but when "humus" bodies are present, nitrites do not occur among the end products, only nitrates and carbon dioxide, together with, of course, dead organisms, the first being relatively large in quantity, the second small, and the last very small.

"Humus," as above stated, does not remain in solution, or suspended for any length of time in the colloidal state, in sea water; consequently in polluted tidal waters nitrites are formed to the exclusion of nitrates. This fact no doubt affords the explanation of the interesting observation made by Dr. Soper in the course of his investigations of the waters of New York Harbour. He has found that decided quantities of nitrites exist in these waters. The sewage from Greater New York is discharged practically in a crude state into the harbour, wherein the solids are deposited and the sewage liquor remains, largely diluted by the river and tidal waters in the same, for several days, and undergoes almost complete fermentation before being gradually carried out to sea by tidal action.

If the character of the bio-chemical changes which these two classes of water bacteria bring about in diluted sewage liquor, as just described, be carefully considered, it will be found that they are quite unusual when compared with the chemical changes which other organisms, higher in the scale of life, bring about in the course of their vital processes.

The mode of nutrition of these bacteria is, in fact, quite unlike that of any other form of life—vegetable or animal.

Mode of Nutrition

It is owing to this unusual mode of nutrition, as well as to their universal distribution, that the impossibility of including them in any scheme of general classification of animal and vegetable life is due.

Their peculiarity in this respect lies in the fact that they obtain the energy they require for carrying on their vital processes from the oxidation of their food materials, and not from the oxidation of any portion of their own substance. They also appear to utilise but a small portion of the energy which they set free in this way for the purpose of their own development and multiplication, unless rise of temperature in their surrounding medium be regarded as a factor involved in their development.

As a result of their peculiar mode of nutrition they convert when amply supplied with dissolved oxygen, the large proportion of upwards of 95 per cent. of the fermentable constituents of the sewage liquor in a polluted wated into the innocuous mineral forms of matter—carbon dioxide, nitrates and humus, and, unlike most animal forms of life, they leave no product of their own action, nor unchanged portion of the sewage that could in any way subsequently become offensive, or detrimental to the stream.

The dead bacteria which have flourished upon the sewage liquor, in common with all the other end products resulting from the fermentation of the sewage matter, form favourable food materials for green vegetable growths, and for other forms of life.

There is a further result which attends the peculiar mode of nutrition of water bacteria in the presence of an ample supply of dissolved oxygen, to which the attention of engineers may usefully be drawn, although perhaps it is of more interest to the chemist than to the engineer. It is that the quantities of dissolved oxygen absorbed, and of the end products formed, on the completion of each stage of fermentation, are constant for similar volumes of the same polluted water.

Bacteria as Scavengers

Such is the efficient and harmless manner, so far as the fish life and the amenities of a stream are concerned, in which bacteria act as scavengers in sewage-polluted waters, always provided that a relatively ample supply of dissolved oxygen remains in the water at all times.

When, however, the conditions are reversed, and the sewage liquor in a stream is in excess of the dissolved oxygen in its waters, the bacteria flourish on the increased supply of food materials in such great numbers that they absorb the dissolved oxygen more rapidly than it can be replenished by the absorption of fresh oxygen from the air.

The first consequence of this is—the oxygen content of the water falls below the minimum level required by the fish and other normal forms of life supported by the stream for the continuation of their vital processes. The bacteria, however, continue to feed and flourish on the sewage matter, and when the dissolved oxygen has been entirely exhausted they obtain, by the exercise of another marked peculiarity in their mode of nutrition, the oxygen which they require for the continuation of their vital processes—that is, by decomposing inorganic oxygen compounds such as nitrates and sulphates—that may be present in solution in the water. When both nitrates and sulphates are absent, then the required oxygen is obtained by the decomposition of organic oxygen compounds; in other words, anaerobic or putrefactive fermentation is set up by the bacteria in the fermentative organic constituents of the sewage matter.

When nitrates are thus robbed of their oxygen, the residual substances are quite odorless and innocuous, and the polluted water remains in consequence inoffensive to smell, although deoxygenated.

When, however, sulphates or organic substances are robbed of oxygen in this way, the residual substances in both cases emit offensive odor, so that the waters containing them are offensive to the smell and in appearance, as well as deoxygenated.

If sulphates are present in a water, sulphuretted hydrogen is produced, and this body forms with any iron compounds that may be present in the polluted water a black sulphide of iron—hence the black or discolored appearance of many highly polluted waters.

It may here be noted, in passing, that the sulphuretted hydrogen and the sulphide of iron thus formed and deoxygenated organic compounds possess the property of very rapidly reabsorbing oxygen when the polluted water containing them becomes mixed with "clean" water. It will be necessary to deal with this point more fully when the disposal of sewage solids comes to be considered. It will then be seen that it is one of great practical importance.

The amount of dilution with "clean" water which must be given to a sewage liquor to ensure the condition that the dissolved oxygen in the mixed liquor and "clean" water shall be in excess of the fermentable constituents of the liquor will depend upon the quantity of oxygen dissolved in the diluting water.

It is well to bear in mind in this connection that under atmospheric conditions unpolluted fresh water can hold only extremely small quantities of oxygen in solution, even when completely saturated at atmospheric pressure with that gas. Thus 100,000 c.c. of fresh water, when saturated with the gas at 60 deg. Fahr., and under ordinary atmospheric pressure, holds only 1 gramme of the gas in solution; while a similar volume of unpolluted sea water can hold still less—only 0.8 gramme—under like conditions.

The actual amount of dilution required by crude sewage, or by partially or by wholly purified sewage matter, has been investigated by the Sewage Commission, and their recommendations regarding the question have been published in their Eighth Report.

For sewage liquor—that is to say, for sewage from which the suspended solids have been removed by efficient sedimentation tanks—the commission recommend a dilution with from 300 to 500 volumes of water of a quality which they define by a certain standard chemical test, and which they term "clean" water.

Required Polution

In the case of a sewage liquor from which the suspended solids have been previously removed by chemical precipitation, they do not require so much dilution—only 150 to 300 volumes of "clean" water.

A sedimented sewage liquor would hold light fermentable organic solids, mostly in the colloidal condition, in suspension, as well as fermentable organic substances in solution; but its combined organic content of a fermentable character would not exceed on an average, 30 parts by weight per 100,000 parts of the liquor.

Hence, when such a liquor is diluted with 300 times its volume of "clean" water—the minimum dilution recommended by the Sewage Commission—the mixture would only contain about 1 part of fermentable organic material per 1,000,000 parts of water.

It is of great practical importance to the engineer to note that when sewage liquor is thus largely diluted, the absorption of dissolved oxygen from the diluting water proceeds at an extremely slow rate, so slowly, indeed, that, in order to detect it by means of a chemical test, a sample of the diluted liquor must be kept in a suitable vessel out of contact with air for several days. To be precise, the total loss of dissolved oxygen shown by a sample of sufficiently diluted sewage liquor, when kept out of contact with air for a period of five days at 65 deg. Fahr., will not exceed 0.4 gramme per 100,000 c.c. of the water.

The rate at which the dissolved oxygen would be replenished in the diluting water and sewage liquor by absorption of fresh oxygen from the air, when exposed to the natural conditions of the stream, would in the case of most rivers and inshore waters be at least equal to the rate of loss indicated by this analytical figure. Hence it may be concluded that, when the discharge of a sewage liquor into a "clean" water stream is properly controlled and limited, it should not, after it has been sufficiently diluted by the waters of the stream, cause an appreciable reduction of the oxygen content of the same waters.

Such, in brief, are the more important bio-chemical principles which underlie the dilution method of disposal for normal sewage liquor.

Disposal of Solid Matters

Adverting now to the question of the disposal of the solid portions of sewage matter, it will readily be understood that water bacteria cannot be relied upon to "mineralise" them when they are discharged into a stream in the same efficient and innocuous manner as they can be in the case of the sewage liquor, simply because these solid portions cannot in like manner be broken up and attenuated by the waters of the stream to anything like the extent of 1 part per 1,000,000, and cannot therefore be adequately supplied with dissolved oxygen during any fermentative change exerted upon them by water bacteria.

If the stream into which they are discharged be not sufficiently rapid to transport and to disperse them through large volumes of "clean" water or over large areas of clean bed, they will be deposited more or less rapidly along the bed; and if they remain there undisturbed for a few days, they will encourage the growth of myriads of water bacteria in and about their mass; and since their fermentable organic constituents would be in large excess of the dissolved oxygen in the water about them, they would undergo anaerobic fermentation, with the attendant formation, as above described. of the offensive gas, sulphuretted hydrogen, of the black sulphide of iron, and possibly also of offensive deoxygenated organic substances, the sulphuretted hydrogen and sulphide of iron being more largely formed in the case of sea waters than in that of non-tidal waters, inasmuch as sea waters hold larger quantities of sulphates in solution.

These products of anaerobic fermentation will tend to poison the bed of the stream in the immediate neighborhood of the deposited solids, and the extent of the injury would depend upon the area of bed covered by them. It is well to remember that comparatively small areas of solid deposits may, if disturbed from time to time, very distinctly reduce the oxygen content of large volumes of waters flowing over them. When, for example, the putrescent solids become disturbed and distributed through the water flowing over them by a freshet in a river after dry weather, or by a spring tide following a neap tide period, they would absorb in a few minutes more or less completely the dissolved oxygen of the water through which they were dispersed, owing to the great chemical affinity which the anaerobic products, above enumerated, possess for dissolved oxygen.

(Concluded in next issue)

The Benefits of Hydrated Lime in Concrete

It has been found in recent years that the judicious use of a small percentage of hydrated lime performs certain functions necessary to good concrete, such as segregation of the aggregates during placing, reducing shrinkage cracking to a minimum and making the concrete watertight, thereby reducing the expansion and contraction of the concrete, due to the absorption and expulsion of water. The use of from 5 to 15 per cent. of hydrated lime, (by weight of the cement ingredient), has been steadily growing in favor with engineers, architects and contractors.

A Factory Built on Concrete Piles

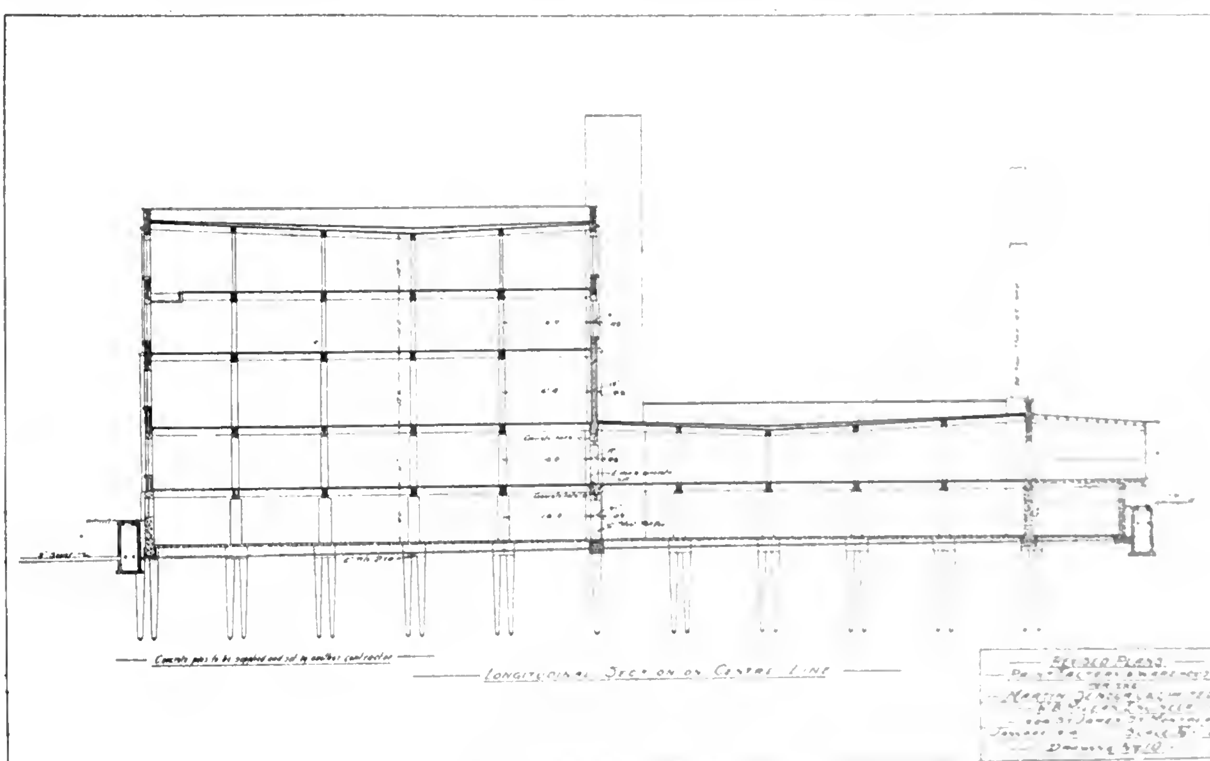
With a view to consolidating their manufacturing facilities the Martin-Senour Company, Limited, makers of paints and varnishes, have just completed a paint factory on a site adjoining their varnish factory at Park Avenue Extension, Montreal. The building is of heavy mill construction, specially designed by Mr. W. B. McLean, engineer, of Montreal, to meet the requirements of the company. The building is in two sections—one of four storeys and the bacement, and the other of one storey and basement, the former being used mainly for manufacturing and the latter for shipping and storage. It is intended later to build additional storage on the shipping and storage end, making the entire building four storeys high. What is now the outer wall up to the shipping room will then be a fireproof wall, from basement to roof, dividing the building into two portions. In plan the building is 180 feet by 80 feet.

Owing to the peculiar nature of the soil, it was necessary to sink about 400 piles for the foundation; this work was carried out by the Raymond Concrete Pile Company of Canada, Montreal. In addition the ground is underdrained, four catch basins, one at each end and one at each side, being constructed. To minimize fire losses and ensure the safety of the employees each floor is entirely separate, and can only be reached from a fireproof stair tower, protected by fire doors at every floor. In this way a fire in any of the departments would be confined to that room. The stairway is of concrete. The elevator runs in a heavy brick tower, also shut off by fire doors at each floor. This tower is extended above the roof to carry the sprinkler tank. The building is of plastic brick, with windows of steel. The floors are supported by beams of Douglas fir, with Duplex hangers and post caps. The roof was built to Barrett specifications. The building is also fitted with an efficient sprinkler system.

The basement is devoted to the storage of raw materials, which are delivered from the railway cars on a siding, the C. P. R. line running alongside the factory. The goods are placed on a covered concrete platform on the first floor level, and from there are lowered by means of a slide into the basement. Under this platform is a basement space which is outside of and separated from the main building. This is used for the boilers, coal pocket and large storage tanks for linseed oil. The oil is raised by air pressure to the upper floors of the factory as required. Putty mixing is carried on in another portion of the basement.

The raw material, after being lowered into the basement, is elevated to the top floor, where are situated the paste mixers; after this operation it is dropped direct into the grinders, which are directly underneath on the floor below. The next process is that of liquid mixing, done on the second floor, the material being lowered direct into the machines from the grinders. The liquid is afterwards pumped into a number of separate mixing tanks on the same floor, the second floor being of a greater height than the others on account of the larger size of the equipment. The paint is now run into separate containers, which are sealed and labelled ready for the storage bins on the first floor, to be shipped as called for. The other portion of the first floor contains the offices, printing room, and advertising department. Each department is operated by electricity, with a motor on every floor.

The general contractors were Messrs. Reid, MacGregor and Reid, Montreal. The heating was carried out by T. H. Higginson, Limited, Montreal, who also installed the sprinklers. Darling Bros., Montreal, were the contractors for the elevators, while the plumbing was done by Mr. John Date, Montreal.



Paint factory and warehouse—Martin-Senour Co., Limited, Montreal.

Better Design of Reinforced Concrete

To Obtain Strength, Toughness, Rigidity with Greatest Economy— Valuable properties lost if work is not properly designed and executed

By M. T. Cantell, Lic. R.I.B.A.*

Reinforced concrete is a combination of Portland Cement Concrete and Steel, two of the most important materials used for construction, which if used separately have each their advantages and disadvantages. If combined, of the right quality and properly proportioned, the resulting material will have the advantages of both and the disadvantages of neither.

Concrete alone has great strength in compression, its crushing resistance when a month old being approximately 2,500 lbs. per sq. inch. It is very durable in any position, is practically everlasting, costs nothing for maintenance and its strength increases with age, but it is of little value in tension, its ultimate resistance being about 200 lb. per sq. inch. It is a good material to resist heat, but it is not elastic or ductile, and owing to the lack of these properties and to its weakness under tension, it will quickly develop cracks in resisting the slightest contraction which takes place under variations of temperature. These cracks, however small, will destroy the slightest tensional resistance the concrete might otherwise offer. Consequently concrete alone can be used for such structures or parts of structures that are in compression, and this, in many cases, necessitates a very large mass of concrete, and consequently, a much greater weight and demand on space than is desirable. An obvious disadvantage of plain concrete is its great bulk and consequent weight and demand on space.

Ultimate Strength of Steel

In steel we have a material of great strength in both compression and tension, its ultimate resistance being as much as from 60,000 lb. to 100,000 lb. per sq. inch, but its strength diminishes with age. This is chiefly due to oxidation which takes place on exposure to moisture, acids or to atmospheric influence. This is very detrimental to its strength, even 1-40 of an inch of rust on a 3-4 inch bar will diminish its strength by 13 per cent. Another disadvantage is its excessive expansion and loss of strength under a high temperature. Steel gains in strength with heat up to 500 degrees F, beyond this it rapidly diminishes in strength. With a rise of temperature from the normal to 500 degrees, a beam 26 feet long will expand one inch. With a rise of 1,000 degrees, it will expand one inch to 13 feet. In ordinary house fires, the temperature seldom exceeds 1,000 degrees, but in large buildings it is known to have exceeded 2,500 degrees. This first attracted particular notice during the inspection of the ruins of the great fire at Baltimore in 1904. It was there noticed that in some of the large buildings brass and cast-iron was entirely fused. Fusion had also taken place on the corners and angles of certain steel work. Here it was also noticed that concrete formed a far better fire protection than terra cotta which has many times been further exemplified since that date. This is owing to the expansion of terra cotta being approximately twice that of steel. Under the above conditions, excessive stress is set up in beams, stanchions and frame structures due to the resistance of their loads and fixed ends preventing longitudinal expansion. This stress far exceeds what the steel is capable of resisting, especially in its weakened condition, the beam or stanchion therefore buckles and causes collapse of the structure. Collapse is often due to the deflection of beams causing eccentric loads of the columns which set up a stress far in excess of what they are capable of resisting. Another disadvantage of steel structures is the comparatively high cost of maintenance, also, the fragile appearance of framed structures suggests weakness rather than strength; these framed structures are also unsightly and cannot be made artistic or pleasing in effect without largely increasing their weight, initial and maintenance costs.

Strength, Toughness, Rigidty

In reinforced concrete properly designed and made, the two materials act together as one. An important point in designing is to see that the materials and methods are such as to insure this being the case. Consequently, we have the strength, toughness and rigidity of steel, the appearance of stability and strength, the steel permanently protected from oxidation, no loss of strength with age, a saving in the cost of construction, speedy erection, very little or no charge for maintenance, and a material adaptable to all forms of architectural and structural work. Furthermore, numerous experiments together with the lapse of time and very severe tests to which it has been subjected in existing structures have proved conclusively its absolute reliability for the construction of structures above ground, below ground and under water, for the workmen's cottages to millionaires' mansions, for business premises, hotels, churches, theatres, public buildings, electric power stations, gas works, factory chimneys, reservoirs, water mains, conduits, sewers, grain elevators, roads, bridges, breakwaters and sea defence works and numerous other purposes. It is a method of construction which is fast superseding that of brick, wood, stone and iron, and is far superior to any one of these in resisting water, fire, earthquakes, atmospheric influence, and even burglar attacks which is a great consideration with the construction of strong rooms for banks and business premises. For even with the oxy-acetylene blow-pipe, the time required to cut an opening through a slab sufficiently large to operate would alone prohibit this method of attack without considering the alarming noise of the lamp during operations.

Of the valuable properties reinforced concrete may possess, few will exist if the work is not properly designed and executed. The latter is quite as important as the former, for if the greatest of care is taken with the design and careless supervision given to the construction the result may be as bad or probably much worse than if the work was badly designed. In fact, a poor design well constructed may give a much better result than a good design badly constructed. The supervision should include careful inspection and testing of all the materials; attention to the preparation; erection and removal of the forms; to the gauge mixing and placing of the concrete; to the size and placing of the reinforcement according to the drawings; to the position and condition in which slabs and beams are left unfinished at the end of a day's work;

*Before the Winnipeg Branch C.S.C.E.

to the condition of unfinished work before its continuation or completion; and to the protection of newly finished work from building operations and inclement weather. All these points are of the utmost importance if we aim at the best possible results. It is, therefore, absolutely necessary that constant expert supervision be given to the construction.

Combine Economy With Strength

In designing, strength is generally considered the chief point. Strength, however, should always be considered together with economy. This has not been done in the past to the extent it should have been and the neglect has been very detrimental to the progress of the work. It has given the public the impression that this method of construction is more expensive than brick, stone or steel, but it is not, there is a great saving in cost on large structures and also on small ones, providing there is sufficient of detail to keep down the cost of form construction. Economy in design has sometimes to be considered from two points of view—the engineering and the architectural—these will not always coincide. The most economical engineering structure would have a certain arrangement of beams, slabs, columns, walls, etc., all spaced and proportioned in the most efficient manner and with a definite percentage of reinforcement all determined with due regard to the loading and with a view to obtaining the strongest, most satisfactory and cheapest structure. But if these engineering points were the only ones considered by the architect, the result in some cases would be very uneconomical. The engineering structure may be considered either a plain mass or a skeleton framework devoid of architectural embellishments. The architectural structure is the engineering structure made more presentable by the addition of fittings and embellishments. Economy on the engineering side is purely structural and in a building it is attained or partly attained by keeping the floor slabs thin, by a free use of beams or columns and keeping the beams thin and deep, also by graduating the columns in size according to their different loads.

Architectural Features

This from an architect's point of view might turn out very uneconomical as it might involve so much additional finishing in the way of cornices and other details, also extra expense to secure efficient light and ventilation than would be the case if thicker slabs with fewer and more shallow beams were used. Therefore, if we wish to design economical structures, there are many factors to consider,—the most important of these, however, are the ones which influence all structures and should be considered by both the architect and the engineer where these are both concerned. They are: (1) The ratio of breadth to depth of beams. (2) The percentage of reinforcement. (3) The general arrangement of layout of beams and columns. In regard to the first factor, the most economical section for rectangular beams is when the breadth is about 1-3 the depth but this gives a deeper beam than is desirable for most purposes. To have less depth means an increase of width which is placing the concrete in a less effective position. Consequently, a larger section would be required. The increase in volume and cost, however, is not great until the width exceeds 0.6 of the depth which is a good proportion for general purposes and is the one largely adopted. The depth of a beam with double reinforcement is less than would be required for a beam with single reinforcement. The second set of reinforcement is added to assist the concrete in taking the compression owing to the depth being insufficient to provide enough concrete for the purpose, but compression reinforcement is always very lightly stressed, seldom to more than 7,500 lb. per sq. inch, which is due to the fact that it cannot be stressed more than m. times, the stress in the concrete surrounding it where m. equals the ratio the moduli of elasticity of the concrete and steel. Consequently, a comparatively large proportion of steel is required to make good for a small decrease in the beams depth. Beams with double reinforcement are very rarely as economical as beams with single reinforcement. Their cost will vary with the ratio of breadth to depth, the percentage of steel and the ratio of top reinforcement to bottom reinforcement.

Percentage of Reinforcement

In regard to the second factor, i.e., the percentage of reinforcement. Attention to this is of the utmost importance, great waste is often occasioned through an excess of steel being used. There is certain percentage that will give the most economic section, it is that which is such as to allow both the steel and concrete to be stressed to their allowable limits at the same time. For instance: if the allowable stress for the steel is 16,000 lb. and for the concrete 600 lb., which are the usual values, the concrete and steel should be so proportioned as to allow these stresses to exist when the structure is fully loaded, we then get the full value out of each material. If one of these materials is understressed, it means there is an excess of that material and consequently a waste. Now for different classes of concretes there will be different percentages of steel required to give this result. The difference will depend on the difference in the strength and on the ratio of the moduli of elasticity of the concrete and steel. For hard stone, granite or gravel concrete the modular ratio equals 15 and the economic percentage of steel for the above stresses equals 0.675. For broken brick or limestone concrete the modular ratio is 18. For cinder concrete it is 30. Now from this it follows that in a beam, floor, retaining wall, or any part of a structure under a bending stress and built of hard stone concrete, the sectional area of the steel for single reinforcement should be 0.675 per cent. of the sectional area of the concrete. If there is more than this it will not be fully stressed, therefore, the excess is waste. If there is less than 0.675 per cent. the concrete cannot be fully stressed unless the steel is overstressed. The reason for this is as follows: In any member of a structure under a bending stress the total tension equals the total compression and the tension at any distance from the neutral axis is equal to the compression at the same distance the other side of the axis, also the stress in the steel at any point is equal to the stress in the concrete at the same point or at the same distance from the axis multiplied by the ratio of the moduli of elasticity. Therefore, if this ratio is 15, the stress in the steel is 15 times as much as the stress in the concrete immediately surrounding it, and it cannot be stressed more under any consideration, unless the stress in the concrete is increased.

Position of Axis

This also, is why the compressive reinforcement in doubly reinforced beams is always so much understressed. Now if the axis is at the half depth, the stress in the steel will be 15 times the maximum stress in the concrete, which is little more than half its allowable limit. Therefore, as the steel takes all the tension, much more steel is required than if it could be higher stressed, but to be so it must be further from the axis. The exact distance will depend upon the ratio of elasticity and the allowable unit stresses. The higher the steel is stressed, the less will there be required to take the whole of the stress with the same quantity of concrete, and the further will the steel be from the axis. From this it is evident that when the steel and concrete are fully stressed the neutral axis must be somewhere above the half depth and it approaches the compression surface as the stress in the steel increases. Therefore, the position of the axis varies according to the value of the ratio of elasticity and the proportion of steel to concrete, and as the area of steel and concrete depends upon the intensity of stress, we may say that the axis varies according to the value of the modular ratio and the proportion of area of steel to area of concrete. Also, the maximum stress in the concrete is to the stress in the steel as the distance of the axis from the compression surface is to distance of the axis from the steel. Thus, referring to Fig. 1. c:t :: n: (d-n) m. Where c = the compression at top of beam, and t = tension in the steel; m = the

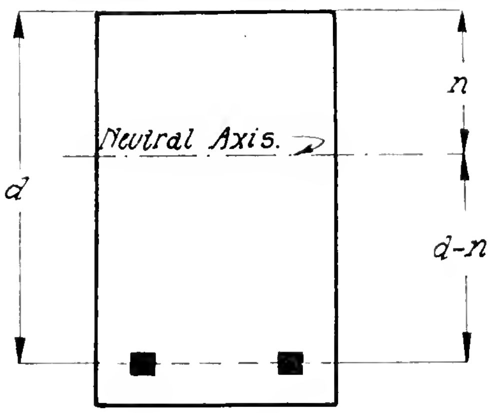


Fig. 1

ratio of the modulii of elasticity of the concrete and steel.

From this we see the error of the early designers in assuming the axis to be at half the depth, we also see that with a certain stress in the concrete for the steel to be stressed to a given amount, it must be at a definite distance from the axis and of a certain sectional area, also that a definite area of steel is required to enable definite stresses to be developed in the concrete and steel. Knowing these fundamentals, there is not much difficulty in designing a beam, the chief factor concerned being the axis and knowing what governs the position of this, it is, therefore, easy to determine. We also know how the stresses vary and that all the compression is taken by the concrete above the axis. With this knowledge, it is only a simple mathematical problem to design a formula whereby we can determine the section of a beam that will contain sufficient concrete above the axis to take the compression, after which we have only to add the percentage of the reinforcement necessary to develop our required stresses.

Materials An Important Consideration

The nature of the materials is a very important consideration. Where strength is the chief point, the concrete aggregate should be gravel, broken granite, trap or similar hard igneous rock. For work up to 3 inches thick, the aggregate should be graded from 3-16 inch to 3-8 inch, and up to 3-4 inch for work 6 inches thick. Above this thickness it may be graded up to 1 inch but not larger. The sand should be quartz, clean and quite free from ligneous organic or earthly matter, and from alkaline or acid pollution. Sufficient should be used to completely fill all the voids in the aggregate with a little in excess.

The cement should be Portland, ground exceedingly fine and in all other respects comply with the standard specification and methods of testing.

The reinforcement should be mild steel. High carbon steel should not be used as its yield point is not so reliable as that of mild steel. It should have an ultimate strength of not less than 60,000 lb. per sq. inch with a yield point not lower than 50 per cent. of the ultimate strength: it should be free from seams and foundry scale and under no consideration should it be painted or galvanized as this prevents the adhesion of the concrete to the steel and thus destroys the bond upon which the theory of design depends.

New Deep Water Terminals, Halifax

(Concluded from page 30)

closely as possible to the natural shore line, so that excavating below water for the required depths would be at a minimum. However, it is necessary to dredge about 250,000 cubic yards of the rock bottom to attain the desired low-water depths (maximum 45 feet), and this spoil is used mainly in filling in behind the walls. This excavation for the most part is in fairly hard rock which requires blasting before dredging; but in some low areas the rock lies at a depth of from 50 to 90 feet and it is necessary to dredge out the overlying mud. In these sections a granite rubble mound is deposited to form a foundation for the quay-wall blocks.

The deep-water terminals at Halifax are being built by the Department of Railways and Canals, under the direction of the Minister, Hon. Frank Cochrane, and under the direct personal supervision of F. P. Gutelius, General Manager of the Canadian Government Railways. Design and construction are in immediate charge of James McGregor as Superintending Engineer, with F. W. Cowie, of Montreal, as Consulting Engineer on the dock works, and C. B. Brown, Chief Engineer of the Canadian Government Railways, as Consulting Engineer on the railway works. A. C. Brown is Resident Engineer on the dock works, R. H. Smith is Resident Engineer on the railway works, and J. J. Macdonald is Office Engineer. The railway grading contract is held by the Cook Construction Company, Limited, and Wheaton Bros., with Andrew Wheaton and I. J. Bowes in charge, and the dock contract by Foley Bros., Welch, Stewart & Fauquier, with J. P. Porter and R. B. Porter in charge of operations representing the company, and J. W. Roland as their Chief Engineer.

The Canadian National Clay Products Association will meet in convention at the King Edward Hotel, Toronto, on January 18, 19 and 20.

The annual meeting of the Canadian Society of Civil Engineers will be held in Montreal, January 25, 26 and 27. President, Mr. Geo. H. Dougal. Secretary, Professor McLeod.

Honors for Canadian Engineers

A keen appreciation is shown of some of our best Canadian types in the engineering and contracting field in conferring new year's honors on such men as Collingwood Schreiber, William Duff Reid, John Kennedy and Sir Thomas Shaughnessy.

Sir John Kennedy, consulting engineer of the Montreal Harbor Board, comes of a family which for many generations has been connected with engineering in one form or another. He is a son of the late Mr. William Kennedy, founder of the firm of William Kennedy and Sons, Limited, Owen Sound. He was born in Spencerville, Ont., in 1838, and educated at Ottawa, and later in McGill University. As early as 1875 he was appointed to the position of chief engineer of the Montreal Harbor Commission, and has had charge of several large works such as rebuilding the Montreal harbor wharves, the deepening of the ship canal between Montreal and Quebec, the entire remodelling of the Montreal harbor and important Government works for the improvement of the deep water terminus of the Intercolonial Railway at Halifax, recently completed. He has also been connected, either as constructing or consulting engineer, with a number of Canadian power projects, including Niagara Falls, Chaudiere Falls, the power plant at Kenora, the Beauharnois plant and a number of others. Sir John was one of the founders of the Canadian Society of Civil Engineers, is past president and an honorary member. He has also served on the board of directors of the American Society of Civil Engineers and on the council of the Institution of Civil Engineers. Since 1907 he has withdrawn more or less from active constructional work, but has been retained by the Harbor Commissioners in a consultant capacity, which position he still holds.

Baron Shaughnessy.

Sir William Duff Reid is a son of Sir Robert Gillespie Reid, and since his father's death, in 1908, has presided over the destinies of the Reid-Newfoundland Company. He was born in Australia in 1867, but came to Canada in 1871 and settled near Galt, where his early education was obtained. His first piece of construction work was about eight miles on the Algoma branch of the Canadian Pacific Railway. Later he had charge of the construction of a branch of the Intercolonial in Cape Breton. Since 1890 he has confined his attention to the business which bears his name, one of the most considerable in extent on this continent. The operations of the Reid-Newfoundland Company on the island of Newfoundland comprise a railway some 600 miles long, an extensive telegraph system, a fleet of steamships and large power developments and manufacturing interests, all operated under the name of the Reid-Newfoundland Company of which Sir John is president and general manager.

Sir Collingwood Schreiber, as far back as 1863, was divisional engineer of the Nova Scotia Government on the Pictou Railway. In 1867 he became associated with the Intercolonial Railway, and in 1873 was appointed chief engineer and general manager of these roads. In 1880 he succeeded Sir Sandford Fleming as chief engineer of the Canadian Pacific Railway Company, and in 1892 was appointed chief engineer of the Department of Railways and Canals, with the additional office of Deputy-Minister of Railways and Canals. In 1905 he was appointed chief general consulting engineer of the Dominion Government and chief engineer of the western division of the National Transcontinental Railway.

Sir John Kennedy.

Sir Thomas Shaughnessy, who now becomes a Baron, has been connected with the Canadian Pacific Railway since 1881, when he was appointed purchasing agent of the company. Ten years later he was appointed vice-president. In another eight years, that is, in 1899, he succeeded Sir William Van Horne as president. The history of Baron Shaughnessy is largely the history of the Canadian Pacific Railway, generally recognized as the best managed steam road on the continent of America. He was born in Milwaukee in 1853. Of all the New Year's honors none resulted from higher merit—none will be received with greater approved by the citizens of the Dominion of Canada.

Some Good Contracts

Cloisonne and Art Glass, Limited, manufacturers of art glass, electrical goods, and ornamental iron work, Berlin, have recently received some contracts, including the following:—

Drumbo—leaded glass, wiring, and electrical fixtures for the new Presbyterian Church.

Preston—wiring and electrical fixtures in the Lutheran Church.

Petersburg—leaded glass in the new Lutheran Church.

Berlin—leaded glass windows in the addition to the Zion Evangelical Church, and glass and sky-light prism for the new Economical Building.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

Sir Robert Borden's New Year's message to the Empire carries with it the hearty endorsement of every Canadian worthy of the name. There may be differences of opinion as to whether the Dominion can raise half a million troops without resorting to conscription, but all are of one mind as regards her intention to try. Everybody is agreed that the war is as much our war as it is the Mother Country's; that our freedom is involved just as hers is. After more than a year of fighting Canadians realize how big is the task that has been undertaken. They also realize that the magnitude of that task proves more than ever how great was our danger. Sir Robert Borden has voiced our unalterable determination to pursue the war to a victorious finish whether it takes half a million or a whole million of our sons and the last dollar that we as Canadians can raise or borrow.

* * *

According to the Canadian Patriotic Fund, several firms engaged in the manufacture of munitions have decided to devote a percentage of their profits to the fund for soldiers' families. And while it may be wrong to look a gift horse in the mouth, it is always well to have an eye out lest the animal have a kick in his left hind leg. This unlooked-for liberality comes on the top of, and perhaps in answer to, a suggestion that war profits be taxed. If this suggestion is acted upon the Government and not the contractor will have the dividing of the profits and the fixing of the share the contractor is to retain. While I believe that individual contractors might act with even unseemly generosity the fact remains that most of the contractors are corporations. And it has yet to be proved that corporations have souls. Then, again, you know certain stocks have been sold because of the dividends the profits assured. Might not an occasional contractor argue that his first duty was to the widows and orphans who had invested in his stock? Taking it by and all, the matter can be viewed from too many different standpoints, and as the result must do the greatest good to the greatest number an independent tribunal must work out that result. That tribunal must also be in possession of all the facts concerning all contracts. So we arrive as usual at the absolute necessity for an investigation of the Shell Committee.

* * *

The report of Sir Alexander Bertram's resignation appears to have been grossly exaggerated. Still there are those who believe that the noble knight will never find his health sufficiently restored to permit of his return to his arduous duties. He has issued two valedictories and received one title. He has explained his position to Sir Sam Hughes and the Toronto Globe. He has not laid down the burdens and cares of office, but he has gone out from among us carrying them with him. It is to be hoped, however, that he will be sufficiently recovered to attend the investigation into the affairs of the Shell Committee which the present session of Parliament can hardly fail to provide.

* * *

Of the $13,000,000 advanced by the Government to western grain growers last spring it is claimed not $1,000,000 has been repaid, and according to the Winnipeg Telegram the farmers are evading payment in the hope that the debt will eventually be cancelled. This, coming on top of the greatest crop in the history of the West, is not encouraging. When the farmer was in need the Government went to his aid; now the Government is in need—of every dollar it can raise or borrow for the purpose of carrying on the war—and the farmer refuses to do his duty. Truly the farmer does not appear in a patriotic or grateful light. Of course the government is secured, but out of a ripe experience the farmer probably figures that a close election might induce a certain leniency. Then again there are stories that shell manufacturers are making enough out of their shell contracts to be able to scrap their plants when the war is over. Does the farmer argue that a Government that buys plants for contractors should also buy seed for farmers? Maybe so. Still, a cry for "free wheat" comes with very poor grace from men who in the hour of need got financial aid from the Government and now in time of their plenty try to evade payment of the money received. And yet if a Government will play practical politics with its people it is not surprising if said people occasionally give the Government a dose of its own medicine.

* * *

Brigadier-General—pardon me, Sir Alexander—Bertram is off to summer lands in search, we are told, of new health, and hurtling through the air in his direction goes a title. And surely no man ever tried so hard to earn the Government gratitude the title implies. Sir Alexander has loaded all the cares, crimes and virtues of the Shell Committee on his shoulders and tried to take them south with him. And the Government cares not where they go so long as they are out of sight and have any kind of a chance of being out of mind. But the public refuses to forget some things—and the Shell Committee is one of them. The public wants to know all about it, and is clamoring for an investigation so insistently and audibly that the Conservative press are hearing it even above the calls of party loyalty. That old-time Conservative organ the Hamilton Spectator is one of the latest to climb the fence and voice the sentiments of its subscribers. The Spectator hasn't made any half-way jump like the Ottawa Journal. It places the responsibility where it belongs—on the shoulders of the government. In an editorial dealing with the Shell Committee the Spectator says:

"Upon the Dominion Government rests the duty of setting on foot a most thorough and rigid investigation of its operations from beginning to end, and we cannot doubt that the ordaining of such an investigation will be regarded as one of the first tasks of Parliament at its approaching session."

How many more prominent Conservative journals will have to speak before Sir Robert Borden realizes that the machine oilers by whom he is surrounded do not voice the sentiments of the people?

* * *

When somebody blundered at Ottawa and the patriotic public was led to believe that our boys needed machine guns, the Montreal Star was one of the first to appeal for funds for the good cause. You'll remember the money came with a rush. Then one sad day it was announced that the machine guns were not needed, or could not be bought —or something. Since that time the Star has been busy refunding money to all applying subscribers. At the close of the year it was obliged to confess that there was still $8,000 in the bank, all ready for some one to prove property and take the animal away. By the way what has happened to the money the Government received for this purpose?

* * *

Is Canada to receive no more shell contracts? This idea prevails in certain quarters. Still it was only the other day that Lloyd George was appealing to the patriotism of Glasgow workmen. And that appeal surely carried a conviction that the Empire needs all the munitions her factories can make. Does it all mean that so far as munitions and munition contractors go Canada is not looked on as part of the Empire but rather as a neutral country? Are our contractors put in the "cold business" class occupied largely by our Yankee cousins? Has Britain refused to forget that when men cried from the trenches for shells the Canadian manufacturer came forward with a dollar's worth of shell in one hand while the other hand was held out for $5.00? Are we to give our sons to the Empire by the half-million and yet to have a cold, hard, commercial rating that belies our loyalty? Is Canada as a whole to suffer that a few may become rich? These are questions we are not to ask. The answers might harm some of our alleged leaders. And we must be loyal to our leaders rather than to the Empire and the freedom the continuance of that Empire assures us.

* * *

We are informed from Ottawa that the work of the Davidson investigating commission is almost finished. To criticize that work would probably be considered contempt of court and I would hate to be the only one to receive punishment at its hands. But I fain would ask a question or two. Surely one may venture that far. And my first query would naturally be: "In the Hopkins investigation was it Mr. Hopkins or Mr. Acton who was being investigated?" And following this would it be unwise or unkindly to ask why Mr. Hopkins was not called to the stand? Mr. Hopkins' home is in Toronto, but he is taking most of his meals at the Biltmore Hotel in New York City. I believe he prefers the New York climate and if he does spend an occasional Sunday in Toronto it is because his family still resides in the Queen City. Of course he might have gone to Ottawa as a witness but those attorneys have a way of talking to mere witnesses that does not make their position in the box an attractive one. Still I believe that Mr. Hopkins could have been persuaded to take the stand. And a lot of people would have read his testimony whether it was interesting or not.

* * *

Henry Ford has returned to the continent and country of which he so proudly forms so large a part. He has learned that while a little thing may start a war it is a man's job to stop it. It has perhaps dawned upon him that he is not that kind of a man.

* * *

And now it is claimed that the Allies are placing orders in the dominions for forty million dollars worth of lumber. Tremendous quantities of it are being destroyed on all fronts every day. Norway and Sweden are being swept clean and the Allies now have to go further afield for their supplies. Add to this the amount necessary to rebuild the various war zones and you'll be prepared to admit that the man who has a timber limit is almost as well off as he who rejoices in a shell contract.

* * *

Sir Sam Hughes, General Logie and others are confident that half a million men can be recruited in Canada. But when you stop to consider that statisticians figure that only ten per cent. of a country's population are available for service you have a doubt. Placing Canada's population at eight millions you would have 800,000 as her total available population for military purposes. It would be optimistic to say the least to expect five out of every eight of those to come out voluntarily and enlist. Still Sir Sam says it can be done. And if you're from Ottawa you know that what Sir Sam says goes.

There have been several additions to the select circle of Canada's aristocracy during the last week or two. I haven't the slightest objection to offer but what with honorary colonels, honorary generals, knights, barons, etc., the upper tiers of this young country are becoming a bit crowded. That chap who said there was plenty of room at the top evidently lived before the present war got in its deadly work.

* * *

Toronto Saturday Night has rushed to the defence of the Shell Committee even while Conservative organs are tumbling over each other to show their independence by demanding an investigation. As a defender of the defenceless the Toronto society paper is in a class by itself. It has long been noted for its tenderness of heart and its disinterested kindness to any and all whose sufferings were called to its notice. The present instance is no case of contracted kindness.

* * *

By the way, where is that amiable young Canadian patriot Hon. W. L. MacKenzie King these trying war times? Is he helping John D. Rockefeller to spend his millions, or is he telling his countrymen to go to war and fight for the county he is so fond of representing? Not so very long ago Mr. King was issuing warnings to the proletariat of Waterloo County that are strangely at variance with the speeches he delivers at patriotic meetings. You'll remember how on one historic occasion he solemnly declared:

"Are the people of this country going to place at the head of affairs a man who takes such a position as Borden was in over a year ago, when he was prepared to take from the treasury of the country, and would have taken it had he been at the head of the Government, enough money to build two Dreadnoughts, to send that money to England, telling them to sink it in warships? The amount of money he was prepared to send there to take out of the treasury to build warships to fight Germany is more than is being spent for the whole service which the Liberal Government is constructing, and which, when built, will remain around our own shores as a protection, and not as jingoes might want to use it."

* * *

"Three million dollars is the value of Manitoba Agricultural College buildings as they stand, including the site and furnishings, according to an official report made to the Government by the Canadian Appraisal Company of Montreal, appointed some time ago to make a valuation of the Provincial buildings. The Agricultural College cost the Province approximately four million, it was stated in Government circles. Where did the other million dollars go?"

Let me see, was not the Hon. Bob Rogers then Minister of Public Works?

SEARCHLIGHT.

Personal

Mr. C. E. Tisdall is the new Minister of Public Works of the province of British Columbia.

Mr. Arthur Reid, Commissioner of Public Utilities for the city of Lethbridge, Alta., has resigned. He is succeeded by Mr. Freeman.

R. J. McClelland, city engineer of Kingston, who applied for and was granted a commission as captain in the 146th overseas battalion, will be unable to go to the front on account of being pronounced physically unfit.

Sergeant A. Grant MacDonald, of the 125th Battalion, formerly Assistant Superintendent of Construction with The Schultz Brothers Company, Limited, of Brantford, Ont., has been transferred to the Canadian Aviation Corps with the rank of Flight Lieutenant. Lieut. MacDonald's departure was made the occasion of the presentation by his firm of a handsome portmanteau.

Mr. P. A. McDonald, Winnipeg, has been appointed Public Utilities Commissioner for Manitoba, succeeding H. A. Robson, who resigned some weeks ago.

Mr. G. W. Caye has been appointed purchasing agent of the Grand Trunk Railway System, with headquarters at Montreal, succeeding J. G. Guess, resigned.

Mr. G. S. Michel, formerly assistant director of Public Works of the Province of Quebec, has been appointed engineer and director of public works, succeeding E. Charest, retired.

Mr. F. B. McFarren, until recently general manager of the Interprovincial Brick Company of Canada, Limited, has received an appointment as Lieutenant with the 83rd Battalion, C. E. F. Mr. E. G. Glen has been appointed acting manager during his absence.

Obituary

Mr. D. Sauve, of Hull, Que., for the last eighteen years employed by the Hull corporation as foreman of works, died last week. Mr. Sauve was well known in Hull, where he had lived the greater part of his life.

Mr. George I. Ainsworth, of Orillia, Ont., died at Guelph recently while on a business trip. He represented the R. A. Lister Company, manufacturers of gasoline engines, Toronto. He travelled over a wide area for them, and was looked upon as an expert in his line.

Mr. W. H. Mitchell, a well-known citizen of Calgary, died recently after a six-weeks' illness. He was a civil engineer, and was engaged in the contracting business for many years. Recently he had been engaged in work for the C. P. R. He was born at Truro, N. S., and lived in Kingston, Ont., for many years, moving to Calgary about nine years ago. A widow and three sons survive him. A fourth son, Robert, fell in the battle of St. Julien last April.

Mainly Constructional

East and West—From Coast to Coast

The Panama Canal has cost the United States $357,436,048. Of this amount $14,689,873 has been devoted to fortifications.

Jas. Worswick Company, Limited, contractors, of Winnipeg, Man., have changed the style of the firm to that of Jas. Worswick, Limited.

There was a decrease of $10,542,399 in the value of building permits issued by the city architect of Toronto during 1915 as compared with 1914.

On December 30th the engineering departments of the city of Saskatoon held their annual banquet at the King George Hotel. Representatives of all the mechanical departments of the city were present, and an enjoyable evening was spent.

The Montreal Council will spend $12,940 on the construction of a purifying pit at the mouth of the Notre Dame de Grace sewer. Controller Cote states that the city must soon be prepared to purify all its sewage before emptying it into the rivers.

Building permits issued by the city of Quebec during 1915 totalled 1444, and amounted in value to $2,578,042. The number of permits issued last year was more than double that of 1914, but the value of the preceding year was greater, the total cost of the new buildings erected in 1914 having been $2,759,573.00.

Judge E. H. Gary, Chairman of the Board of Directors of the United States Steel Corporation, says that the present rate of production of steel ingots in the United States is about 41,000,000 tons per annum. The previous best record was 35,000,000 tons in 1913.

Mr. Ernest Drinkwater has been reappointed engineer for the corporation of St. Lambert, P. Q. Mr. Drinkwater was originally engaged for three years as town engineer, and as the term expired recently, it was necessary for the Council to make a further appointment.

The Western Machinery Company, Limited, has been formed at Port Arthur, Ont., with a capital of forty thousand dollars, to manufacture machinery, boilers, iron and steel, etc. The provisional directors are R. B. Roberts, P. D. Munroe, A. McPherson, W. F. Langworthy, and L. McComber.

Building figures of Windsor, Ont., for December show an increase in value of $82,730, compared with the corresponding month in 1914, the total being $127,600. Figures for the whole of 1915 show building operations decreased to the extent of $475,548, as compared with 1914, when the total value was $1,121,413.

A statement of building permits for the town of Welland, just issued by Mr. D. T. Black, town engineer, shows a total for the year of $191,232 as against $337,918 in 1914. The month of December, 1915, with $19,635, showed a marked increase over the same month in 1914, when permits amounted to only $2,250.

The Chatham, Ont., branch of the Builders' Exchange met recently to do honor to two of their members, Mr. Arthur Back and Mr. W. Boa, who have enlisted with a Hamilton regiment. There was a large attendance, and a splendid banquet was served, after which Messrs. Back and Boa were presented with wrist watches.

The report of the building inspector, Mr. S. M. Jarrett, of Vancouver, B. C., for December, 1915, shows that the total value of permits granted for the month was $27,180 as compared with $39,765 in the same period in 1914. The value of building permits for the twelve months of 1915 was $1,593,279 as against $4,484,476 for the previous year.

The Consolidated Steel Company, Limited, Toronto, have obtained a charter. Their capital is one hundred thousand dollars, and they will carry on the business of iron founders, mechanical engineers, manufacturers of machinery, builders, electrical engineers, etc. The provisional directors include William H. Beatty, F. A. Hammond, and C. B. McClurg—all of Toronto.

The contractors who aided in the work of building the new Hotel Vancouver, Vancouver, B. C., were entertained on December 28 at a banquet given by Messrs. Skene & Christie. The menu was a unique creation. It was "done" in blue print and contained "specifications" of the banquet, listing the eatables as "primings," "foundations," "sub-basement," "basements," "ground floor," "Mezzanine," "typical," "roof garden," etc.

A report of building statistics for the city of Montreal for the past year just issued by Mr. Alcide Chausse, architect and superintendent of buildings for the city, indicates that the total value of 2,081 permits for 1915 was $8,511,221 as against a value of $17,394,244 for 3,629 permits in 1914. For the month of December alone, 1915, 104 permits represented a value of $2,044,425 as against $361,135 for 144 permits in 1914, indicating increased activity in the larger type of building construction work.

Application will be made to the Quebec Legislature by the Vercheres, Chambly and Laprairie Tramways Company to construct an electric railway on the south shore of the St. Lawrence, with the right to enter Montreal. It is proposed to conduct operations between Saint Roch and Chateauguay, and from Laprairie to Chambly, with loop lines and connection branches to other places in the counties of Chateauguay, Laprairie, Chambly, Vercheres and Richelieu, and across the St. Lawrence River to Montreal.

Seattle, Wash., is to have what its builders declare will be the largest and finest salt-water natatorium in America. Plans have been completed and contracts let, and May 15 set as the definite day of opening. The building, of steel and glass, and architecturally one of the most distinctive in the West, will occupy a site fronting 180 feet on Second Avenue and 108 feet on Lenora Street. The natatorium will represent an investment of $200,000, exclusive of the site, which is under a long-time lease from Mr. Charles D. Stimson.

A large delegation composed of representatives of all the parishes between Levis and Rimouski, recently waited on the Hon. J. A. Tessier, Minister of Roads for the province of Quebec, asking that a modern highway be constructed from Levis to Fraserville and Rimouski. It was pointed out by the various speakers that the construction of such a highway would not be difficult, as there was already a good roadbed over the greater part of the way. The advantages of such a highway, following the course of the river, for tourist travel and for the development of agriculture would be immense. The Minister promised to confer with his colleagues on the matter.

The official statement of the Montreal city public works department, under Mr. Paul E. Mercier, chief engineer, shows a considerable reduction in the proposed expenditure for the current year. The total is $1,646,137, including $413,475 yet to be voted for the roads department, outside, against $1,867,505 last year and $2,715,072 in 1914. Considerable economies are estimated in practically all the departments, the engineers' office being put down at $24,150 instead of $30,150. There is a cut of $21,150 in the estimated cost of repairing roads, the total being $196,170; the city has now 196.17 miles of paved roads, an increase of 40 miles, but in spite of this, less money will be available for repairs.

The Court of Appeals of the Dominion of Canada have awarded Messrs. J. A. McIlwee & Sons, the firm of Denver engineers who drove the five-mile railroad tunnel through the Selkirk Mountains, a verdict of $800,000 against the Canadian Pacific Railroad Company. For certain reasons the company cancelled the contract. The engineers sued in the British Columbia Supreme Court for breach of contract and for the bonuses then due. They were awarded $527,000. The Canadian Pacific then appealed the decision, but the Court of Appeals not only upheld the award in favor of McIlwee & Sons, but increased it to $800,000. The Canadian Pacific have now appealed that award to the British Privy Council.

Mr. John Hartnett, of Toronto, has completed the work of installing the water-works system in Hespeler, Ont. The reservoir has a capacity of two hundred thousand gallons. It is fed from two artesian wells, with apparently an abundant supply of water. The capacity of the standpipe is one hundred thousand gallons, and it gives a working capacity of from twenty to one hundred pounds pressure. The town system has just been connected with the R. Forbes Company's system. In case of a big fire the Forbes Company's pumps would be able to give three thousand gallons a minute into the town's mains. The town pumps could give eight hundred gallons a minute, making this a duplicate system if so required.

Every effort to unravel the mystery surrounding the disappearance from the city of Calgary's vaults of the documents in connection with the proposed new three million dollar Elbow River water-works scheme has been unavailing. The maps, records, etc., represent $10,000 worth of work, and would cost approximately that sum to replace should the city ever decide to go on with the work, and their loss is a serious embarrassment to the city. The missing records vanished from the big safe in the engineer's office some time in May last. The fact was kept a close secret for months in the hope that some clue would be found that would lead to the recovery of the documents and the apprehension of the thief.

Mr. H. P. Borden, assistant to the chief engineer for the Quebec Bridge, says that if the programme of work as outlined is carried out it will be possible to run trains across the bridge at the close of next season. By October the great suspended span, which is 640 feet long, and weighs 6,000 tons, will be floated to its place. This great undertaking was begun nearly eight years ago by a private firm. Subsequently the bonds of the company were guaranteed by the then Government. During its first construction the bridge gave way, and some 95 people lost their lives. The Quebec Bridge was one of the legacies inherited by the present Government. When finished it will have cost some seventeen million dollars. It was at first calculated that the bridge could be built for six million.

France, with all her troubles of the last year and a half, has been able to develop one new industry not connected with war munitions. The French are now said to be turning out excellent cement from a by-product in the process of making beet sugar. From 70,000 tons of beets treated, more than 3,000 tons of cement, equal in quality to the best Portland, is obtainable, purely as a by-product. The scum which forms when the beets are boiled, and which hitherto has been thrown away, is pumped into large tanks, where it is allowed to dry partially. Finely divided clay is mixed with it, and the mixture is thoroughly amalgamated by beaters for an hour and then burned in a rotary kiln, just about as Portland cement is treated. The clinker is removed and pulverized into cement. The best scum, formerly a waste product, was found to contain large quantities of carbonate of lime and water. Four thousand tons of this carbonate is obtained from 70,000 tons of beets. To this is added 1,100 tons of clay, the resulting product being 3,162 tons of excellent cement.

Quantity Surveying

One is just a bit surprised to know that St. Louis is going to give the quantity surveyor idea a trial; it is not a trial, by the way; they have adopted the idea. The civil engineers of that city are responsible for it. Following a campaign by civil engineers, through their organization, the city assembly passed an ordinance authorizing the mayor, with the approval of the council, to appoint quantity surveyors. The number is not limited. The appointees must be skilled in building construction or estimating. They must give bonds in $10,000. Patrons of quantity surveyors, who sustain loss by reason of their negligence, incompetence or misconduct can sue on the bond any time in five years. The charges authorized are the fees agreed upon between surveyor and clients, until a list of fees can be prepared by the Engineers' Club, St. Louis Chapter, A.I.A., and the Building Industries Association. Supplementing the ordinance of St. Louis a state law is being prepared requiring a detailed quantity list with every architectural and engineering plant.—Architect & Engineer.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Amherstburg, Ont.
C. H. Leslie is considering the purchase of a quantity of 4-inch and 5-inch drain tiles for work to be done in the spring.

Cornwall, Ont.
A by-law has been carried authorizing the construction of a waterworks system at a cost of about $25,000. In connection with this, the Town Council will require one steam pump, two boilers, turbine, water pump, and a quantity of 6-inch and 8-inch cast iron pipe. Clerk, J. G. Harkness.

Kingsville, Ont.
The Town Council are considering the construction of a sewage system next summer. Clerk, George Pearse.

Meaford, Ont.
The by-law authorizing the expenditure of $4,000 on extensions to the watermains has been carried. Work will start in the spring. About 2,000 feet of 4-inch pipe and 40 house connections will be required. Town Clerk, G. J. Albery.

Ottawa, Ont.
The by-law providing for the construction of a driveway along the Rideau River has been carried. City Engineer, F. C. Askwith.

Sarnia, Ont.
The by-law to authorize the extension of the watermain system has been carried. Approximate cost, $12,000. City Engineer, John A. Baird.

Whitney Township, Ont.
The Provincial Road Commissioner, J. F. Whitson, Toronto, has decided to remetal the road between South Porcupine and Timmins. Work will start in the spring. Estimated cost, $50,000.

Railroads, and Bridges Wharves

Berlin, Ont.

The Yorkton Creamery Company have let a contract for a cold storage installation at their premises on Lauria Street to the Linde Canadian Refrigeration Company, 909½ Main Street, Winnipeg.

Residences

Avonbank, Ont.
A. Ready, St. Paul's Station, will commence the erection of a residence in the spring. Pressed brick construction.

Brooklin, Ont.
W. A. Dryden is having sketch plans prepared for a residence, estimated to cost $5,000. Tenders may be called in the spring. Brick construction.

Kingsville, Ont.
Wigle & Wright are considering the rebuilding of the residence which was recently destroyed by fire.

London, Ont.
All work required in connection with the residences which are now being erected by the Copp Syndicate will be done by the owners. Secretary, A. M. Hunt, Dominion Savings Building.

Montreal, Que.
Work has been started by Owen Roberts, 112 Addington Avenue, on the erection of twelve flats on Wilson Avenue. Brick construction, concrete foundation, felt and gravel roofing. Approximate cost, $18,000.

J. A. Bray, 6375 Berri Street, is receiving tenders on all smaller trades required in the erection of three flats on St. Denis Street. Brick construction, concrete foundation, felt and gravel roofing. Estimated cost, $7,000.

Ottawa, Ont.
A. W. Davidson, 69 Grosvenor Street, has commenced the erection of a residence on Hopewell Avenue, estimated to cost $4,000.

St. John, N.B.
R. A. Corbett, 274 Douglas Avenue, has commenced the erection of apartments, estimated to cost $3,000. Frame construction, concrete foundation, asbestos roofing.

Tillsonburg, Ont.
F. K. Wilson, Bidwell Street, is considering repairs to his residence.

Toronto, Ont.
George Edwards, 1028 St. Clair Avenue W., has commenced the erection of a pair of residences at 209 Lauder Avenue. Smaller trades will be let. Brick construction, shingle roofing. Estimated cost, $6,000.

Work has been started by F. H. Miller, care of Miller & Sons, Lauder Avenue, on the erection of two residences, estimated to cost $5,500. Smaller trades will be let. Brick construction, shingle roofing.

Whalen, Ont.
Plans are being prepared by James Kelly, Cedar Swamp Farm, for the erection of a residence. Frame and white brick construction, stone and concrete foundation, shingle roofing. Estimated cost, $3,000.

John Foster is having plans prepared for a residence, estimated to cost about $3,000. White brick construction, stone and concrete foundation, shingle roofing.

Plans are in progress for a residence to be built for Richard Hodgins. White brick construction, stone and concrete foundation, shingle roofing. Approximate cost, $3,200.

Wolfville, N.S.
Clark Gormley contemplates the erection of a tenement block in the spring. Frame and stone construction, concrete foundation, wood roofing. Estimated cost, $5,000.

CONTRACTS AWARDED

Fort Erie, Ont.
E. W. Near has commenced the erection of a residence on River Road for J. B. Ernsmere. Frame construction, concrete foundation, shingle roofing. Approximate cost, $3,000.

Maisonneuve, Que.
In connection with the residence which is being erected on LaSalle Avenue by J. T. Legault, 30 St. James Street, Montreal, the contract for plastering has been awarded to D. Thibault, 610 Orleans Avenue, and the electrical work to J. A. Gagnon, 733 Notre Dame Street.

Walkerville, Ont.
The following contract have been let in connection with the residence now being built on River Front for T. McGregor, 239 Brush Street, Detroit:—carpentry and roofing, W. Dupuis, 147 Dougall Avenue, Windsor; painting, Chauncey Bennett, 22 Assumption St.; heating, Windsor Hardware Company, 71 Sandwich Street E., Windsor; plumbing, Pennington & Brian, 47 Sandwich Street W., Windsor; electrical work, Gas & Electric Supply Company, 20 Sandwich Street W., Windsor.

Windsor, Ont.
The contract for heating required in connection with the terrace which has been erected for Mrs. E. M. Rolph, 22 Bruce Avenue, has been awarded to Philip Dresch, 2 Ontario Street, Walkerville.

In connection with the residence erected for John Hubner, 188 Dougal Avenue, the heating contract has been let to the Windsor Hardware Company, 71 Sandwich Street E.

The general contract for the erection of a residence for J. L. Ouellette, 59 Campbell Avenue, has been awarded to A. L. Ouellette, 110 Goyeau Street. Brick construction, concrete foundation, shingle roofing. Approximate cost, $4,500.

Power Plants, Electricity and Telephones

Brantford, Ont.
A by-law has been carried authorizing the sale of the Galt-Paris portion of the Brantford to Galt Municipal Railway to the Lake Erie & Northern Railway. The latter Company will now electrify their road from Galt to Port Dover.

Gravenhurst, Ont.
The by-law authorizing the changes to the street lighting system has been carried and the work will be done under the supervision of the Commission. Town Clerk, W. H. Butterworth. Approximate cost, $3,500.

Noelville, Ont.
W. Davurt is considering the construction of a telephone line between Rutter and Monetville.

Sarnia, Ont.
A by-law has been carried to provide for the installation of a hydro electric system. City Clerk, James D. Stewart.

A by-law has been carried authorizing the purchase and remodelling of the generating plant and distributing system of the Sarnia Gas & Electric Light Company at a cost of $120,000.

Sherbrooke, Que.
The City Clerk, E. C. Gatien, will receive tenders until noon, January 17th, for the supply of transformers. Specifications, etc., at office of the Clerk and of the Engineer, M. A. Sammett, 301 McGill Building, Montreal.

The City Council have awarded the contract for alterations to the power plant to the Jenckes Machine Company, Limited, Lansdowne Street. Approximate cost, $3,740.

Toronto, Ont.
The Board of Control will receive tenders until February 1st on the supply of a number of street cars and equipment and a quantity of copper cable. Specifications, etc., at Room 12, Works Department, City Hall.

The Goldie & McCulloch Company, Limited, Traders Bank Building, are in the market for one direct connected generator, including engine, 25-50 volt, direct current.

Wellesley, Ont.
A by-law has been carried authorizing the borrowing of $7,500 for the construction of an electric light and power distribution plant.

Fires

Caraquet, N.B.
The Sacred Heart College has been totally destroyed by fire. Loss, $250,000; insurance, $100,000.

Cassilis, N.B.
Fire has entirely destroyed the residence and outbuildings owned by Mrs. John Menzies. Loss, about $3,000.

Clinton, Ont.
The store owned by F. H. Powell has been destroyed by fire. Loss covered by insurance.

Fort Frances, Ont.
Fire has destroyed the store owned by G. A. Stephen, Scott Street. Loss is considerable.

Kingsville, Ont.
A residence on Division Road, owner by Wigle & Wright, has been destroyed by fire.

Les Eboulements, Que.
Fire has destroyed the residence of Amede Bergeron. Loss covered by insurance.

Low Point, N.S.
The Roman Catholic Church has been completely destroyed by fire. Loss, about $25,000, partially covered by insurance. Steps will be taken at once to rebuild. Pastor, Rev. Father McAulay.

Middle Sackville, N.B.
The residence of James McInnis has

been destroyed by fire. Loss, about $2,000, partially insured.

Fire has entirely destroyed the store owned by James Smith and occupied by Tillman A. Cormier.

Napanee, Ont.
The residence of F. Asselstine, Isabella Street, has been entirely destroyed by fire.

Quebec, Que.
The factory of the Rock Shoe Manufacturing Company, 166 St. Helene St., has been destroyed by fire. Loss, $75,000, insurance $35,000.

Fire has done considerable damage at the Quebec Seminary. Proctor, Rev. Odilon Gosselin.

The residence of E. Lamontagne, Domaine Lairet, has been destroyed by fire. Loss, $6,000, covered by insurance. Owner will probably rebuild.

Sackville, N.B.
A residence owned by Charles Fawcett Company, Limited, Main Street, has been totally destroyed by fire.

St. Jerome, Que.
The flour mill owned by Edmond Langevin has been destroyed by fire.

St. Joseph, Que.
Fire has destroyed the hotel belonging to Thomas Cliche.

Sydney, N.B.
The hotel owned by the King George Hotel Company has been completely destroyed by fire. Loss, $70,000, partially covered by insurance.

Thorold, Ont.
The store and residence belonging to C. Geracitani has been entirely destroyed by fire. Loss, $5,000, covered by insurance.

Miscellaneous

Chatham, Ont.
The by-law to provide for the expenditure of $15,000 on the purchase of fire equipment has been defeated.

To Study Advantages of Use of Hydrated Lime in Concrete

To determine if the claims that the addition of hydrated lime to concrete increases its plasticity, decreases segregation and improves its waterproofing qualities are justified, the U. S. Bureau of Standards will make tests on such concrete. Before entering into the work an advisory committee, composed of representatives of the four interests involved—the cement industry, the lime industry, the engineer and the contractor—was asked to participate in outlining plans for the work. This committee, which was selected by P. H. Bates and W. E. Emley (of the Bureau of Standards), who will have active charge of the work, met in Pittsburgh, November 4, and offered criticisms of the plan of work prepared by the Federal bureau. As a result the programme was modified to meet such criticisms insofar as was advantageous, and it is expected that the research will be started during the present month.

As outlined, the work is extensive in scope. The tests will include: Determination of compressive strength, expansion, reinforcement, permeability, action of sea water, the hydration of cement, absorption, segregation, abrasion and adhesion of cement to reinforcement. Specimens to which varying proportions of hydrated lime have been added up to five years of age will be tested.

Cover Steam Pipes to Save Coal

One reason for coal costs in the power plant of a clay works being higher than they should be, is found in insufficient covering on steam connections. The proper insulation of steam pipes is important. For instance, in one industrial establishment in a main sixty feet long, the steam was found to contain thirty-one per cent. of moisture. After covering the pipe with a good heat-insulating material, this percentage was reduced to three and six-tenths.

Among the best of the substances available for this purpose are hair-felt, slag-wood, magnesium and asbestos. Hair-felt, while unexcelled as a non-conductor, quickly chars unless protected from actual contact with the piping, by a wrapping of asbestos paper or other non-burnable material. Slag wool, on the other hand, is fireproof. A covering compound of which asbestos fibre is the base, enjoys considerable popularity. It has the advantage of being in convenient form to apply, and also may be used over again. Water, obviously, should not be allowed to drip on the covering, as it not only may soften it so as to cause it to drap off, but a wet covering is a very poor retainer of heat.

Tenders and For Sale Department

Concrete Mixers

Large company in Middle States making concrete mixers wants selling agents for Canadian territory. Good working arrangement and substantial assistance will be given to reliable aggressive agents. Box 279, Contract Record, Toronto, Ont. 1-4

Quarry Machinery Wanted

Two gang saws and one planer in good working order.

F. ROGERS & COMPANY,
1193 Queen Street West,
Toronto, Ont.

1-2

School Tenders

Tenders for all trades in connection with the erection of addition to St. Joseph's, St. Clare's, and St. Anthony's Separate Schools and new school for St. Monica's Parish, for the Separate School Board for the City of Toronto, will be received until 5 p.m., **Wednesday, January 26, 1916**, at the office of the Board, 67 Bond Street.

Tenders to be submitted on forms supplied and to be addressed to E. F. Henderson, Chairman of Sites and Buildings Committee, and to be accompanied by a marked cheque for 10 per cent. of the amount of tender.

Plans and specifications may be seen at the office of the Architect, Charles J. Read, Rooms 203-4 Confederation Life Building, Toronto.

52-2-3

Tenders for
STREET CARS

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon, on **Tuesday, February 1st, 1916**, for the supply and delivery of:-

	Tender Numbers
Street Cars, Complete	70
Street Car Bodies	70-A
Street Car Trucks	70-B
Street Car Motor Equipment	70-C
Street Car Air Brake Equipment	70-D
Copper Cables for Street Car Work	70-E
Street Car Fare Boxes	70-F

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of City By-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman, Board of Control.

Toronto, December 30th, 1915. F

Notice to Contractors

Cast Iron Pipe

Sealed tenders, addressed to the Chairman of the Water Works Committee, will be received by registered post by the Secretary of the Water Works Committee, City Hall, Ottawa, up to 4 p.m., **Monday, January 24th, 1916**, endorsed "Tender for Cast Iron Pipe."

Any tender received after the above stated time will be declared informal.

Specifications and full information may be obtained on application to the City Engineer's Office.

The Corporation does not bind itself to accept the lowest or any tender.

R. L. HAYCOCK,
Acting W. W. Engineer.
City Hall, Ottawa,
January 10th, 1916. 2

Late News Items

Calgary, Alta.
A petition has been presented to the City Council asking for the construction of a concrete bridge over the Bow River at Ninth Street W. Clerk, J. M. Miller.

Cobden, Ont.
A by-law has been carried authorizing the expenditure of $20,000 on the purchase of a site and the construction of plant and equipment for a hydro electric system. Clerk, J. R. Warren.

Grand'Mere, Que.
The Town Council have extended the time for receiving tenders on the supply of electrical equipment until January 14th. Secretary, Louis Berube.

Grey Township, Ont.
The Trustees of School Section No. 10 are considering the erection of a school at an approximate cost of $5,000. Architect not yet appointed. Secretary, William Whitfield, Brussels, Ont.

Halifax, N.S.
Work has been started on the construction of a wharf for the Furness Withy Company, Water Street. The masonry, carpentry and roofing contract have been awarded to the general contractors, Nova Scotia Construction Company, 159 Upper Water Street. Remaining contracts will be let in the spring.

Hepworth, Ont.
A by-law has been carried providing for the loan of $12,000 to the Hepworth Silica Pressed Brick Company, Bruce Street, for the construction of a brick manufacturing plant. Manager, C. S. Block.

Highgate, Ont.
Plans will be prepared at once for the installation of a hydro electric system, estimated to cost $7,000. The by-law authorizing the construction has been carried.

North Caradoc, Ont.
The erection of a school is being considered by the School Trustees. Estimated cost, $5,000. Architect not yet appointed. Reeve, T. G. Turnbull, Komoka, Ont.

Regina, Sask.
The Imperial Oil Company, Limited, Dominion Bank Building, Toronto, have secured a site between Winnipeg Street and the Canadian Pacific Railway, and propose to commence immediately the construction of an oil plant. The railway companies are making arrangements for the construction of the necessary trackage and the city for sewers and watermains. Approximate cost, $600,000.

Sault Ste. Marie, Ont.
The brick residence owned by A. C. Boyce, M.P., has been destroyed by fire. Loss is heavy.

Shawville, Que.
Tenders on the installation of interior fittings at the Post Office will be received until 4 p.m., January 18th, by R. C. Desrochers, Department of Public Works, Ottawa. Plans and specifications with John Shaw, Clerk of Works, Shawville, and at the Department.

Woodstock, Ont.
The by-law providing for the construction of extensions to the storm sewer system has been carried. Work will probably be carried on during the winter. Engineer, J. F. Ure. Estimated cost, $25,000.

Wyoming, Ont.
A by-law has been carried authorizing the construction of a hydro electric system at an approximate cost of $6,000. Plans will be prepared at once and work will commence in the spring. Town Clerk, H. G. Taylor.

Cut Down the Water Bill

For plants that are using town or city water, one way to cut costs is to obtain a private source of supply. A company in Dayton, Ohio, recently saved enough in only a few months, after installing its own deep well and pumps, to pay for the equipment.

Not always can water be secured in this way which is as well suited to boiler use or for tempering as the municipal supply, but when the quality is satisfactory, the saving is likely to be considerable. Then, too, with a private supply there is an added security that comes of having an independent source in case of fire.

Deep wells are often pumped by compressed air. The method is known as the air lift. In this, an air line within the well pipe discharges compressed air at the bottom of the well. These air bubbles lift the water with them as they rise to the outlet pipe.

Sands and solids in the water are no detriment with the air lift pump. In fact, the air lift draws them out and thus enlarges the water bearing cavity and so increases the flow of water.

Politicians vs. Engineers

"The politicians of Canada are going to get a jolt in the next ten years and it is going to come from the engineers"

This is the recently expressed opinion of a business man of the city of Ottawa—the centre of Canadian political activities, intrigues and trickeries, the scene of extravagant spending of the Canadian people's money, the home of incompetence in the discharge of the Canadian people's business. Politicians! This word is associated today in Canada with all that is loathesome to the honest business man. The very scorn of it keeps worthy men from offering their services to their country. It is the final anathema hurled at an enemy when all other words in the English language fail to reach their mark.

The individuals who at election time aspire to "attend to" the business of our country naturally fall under four fairly distinct sub-headings. These are: dishonest incompetents, honest incompetents, dishonest competents and honest competents. The first do as much harm as they can, the second would have our sympathy if we did not have to bear the consequences, the third class represent a very real and dangerous enemy of our country's well-being and the fourth—get defeated at the polls.

The question before the Canadian people plainly is then: How can we increase that fourth class—honest competents—and everything points to the engineering profession. To begin with the engineer is, by training and experience, efficient,—the first requisite of a successful business man whether in private or public affairs. And next, he is honest, from the very nature of his calling. An engineer is an engineer because that particular work had more attraction for him than a business in which the sole or main object is the making of money. And, after all, it resolves itself largely into this—that the man whose ideal in life is "money" has no possible right in our legislative halls.

Will the engineer step in to fill the gap? We hope so. There is no doubt of his fitness. But the country is still shackled with the iron chain of "party" politics—the system that pre-supposes dishonesty and incompetence in that it appoints one man to an office and a second man to watch him. The engineer stands for competence and honesty. Does our country want them?

More Detailed Specifications

MR. O. W. SMITH, in his article on "specifications" reproduced on other pages of this issue, voices once more the ever-recurring protest against the incomplete specification. The difficulty of obtaining fully detailed information as to what is really wanted when bidding on work is one of the serious problems which confronts the contractor. Information of local conditions, for instance, which often has an important bearing on the ultimate cost of the work, is not included in the specifications, even when it is in possession of the designer or the engineer, and the contractor is left to shift for himself and get, as well as he can, such information.

In the ordinary class of straight contract in which the parties are bound within definite and prescribed lines, too much care cannot be taken in drafting the specification which becomes a vital part of the contract. The chief duties of the specification are to define or describe the work, so that any competent contractor may submit an intelligent bid, and to establish a guide and a standard by which the contract may be interpreted to each party. We often find, however, as already stated, that detailed information is not fully given. It is the duty of engineers or writers of specifications to provide positive information of local conditions pertaining to the work above ground and below. The time allotted to the contractor is often too short to admit of anything but a brief survey of conditions and he has to practically guess about conditions which are of vital importance. Clearness, brevity and consistency are three things to be attained in wording a specification. Tautology should be avoided.

To establish a guide and a standard by which the contract may be interpreted with fairness to each party several things are essential, such as—a complete list of quantities of all work, a schedule of unit prices of all items in the work, a schedule of prices for all extra work, and all items in the schedule of prices should be adequately covered by a corresponding clause or section on the specification. Bidders should not be required to estimate their own quantities. The bidder, while perfectly competent to construct the work, may not be expert in calculating quantities.

The gist of the matter is to give all the necessary information in a specification, whether it be description of work and material, local conditions, quantities, matters of extra work, etc., and to have it properly expressed so that all bidders may precisely and explicitly know what is required of them. The more doubtful a bidder is as to what is expected of him, the greater the sum he will add to his price for contingencies which may arise.

The penalty clause should be used only in exceptional cases where it is an absolute necessity to complete within a certain time. It seems ridiculous to have a time penalty clause placed indiscriminately in all contract specifications, when in nearly all cases the contract will be carried out along the usual lines as rapidly as possible.

During the process of developing specifications it would appear that the general clauses, relating to the rights, duties, and obligations of the contracting parties, and the engineer or owner, have received more cultivation than the specific clauses, relating to the description of the work, whose accomplishment is the object of the contract. No one will object to the proper safeguarding of the interests of the owner or public but this can best be done by a fair bargain in which each party knows thoroughly what is required, and each makes himself responsible for his own particular part of the contract, agreeing on a fair method for adjusting unforeseen contingencies which are usually bound to occur.

Hardwood Floors in Fireproof Buildings

In discussing floor surfaces in fireproof buildings in a paper read before the American Society of Mechanical Engineers, Sanford E. Thompson pointed out the kinds of hardwood floors best adapted for the purpose and also the method of laying them. The following extracts from the Architect and Engineer are likely to prove of interest:

Floors of maple, birch, beech, oak, or long leafed Southern pine are used most largely for offices, class rooms, or lecture rooms, and in many of the older colleges for laboratories and halls. A wood surface, however, is not usually considered entirely satisfactory, either in general appearance or in wearing qualities. If one passes from a corridor with a granolithic, terrazzo, or tile floor, into a room or auditorium having a wood floor, there is a marked effect of inferiority and cheapness.

There is just as much danger of poor materials and workmanship with wood as with other kinds of floors. Unless the greatest care is taken in selection of materials and workmanship, they are liable to shrink or swell and sometimes to squeak under foot. If at all hollow underneath, they are more noisy than a concrete surface.

For corridors, wood is being largely superseded by granolithic, terrazzo, or tile. For laboratories other materials are being substituted for wood in most of the newer structures, although wood is occasionally preferred, especially for physical laboratories and for laboratories where men stand for long periods. The linoleum on concrete will overcome practically all the objections that are made to wood floors, with a cost substantially the same.

There are various methods of laying hardwood floors. For class rooms a single thickness of maple or birch nailed to sleepers with cinder concrete between should be satisfactory. Another type of construction is to use patented metal screeds embedded in the base concrete, and nail the floor boards to splines in the screeds. For rooms subjected to heavy traffic, 2-inch or 2½-inch plank may be placed underneath the hardwood floor.

Of all the different materials, oak is the most expensive and the finest in appearance at the beginning, but under heavy traffic is more liable to splinter than the finer grained woods. Georgia pine, if of best quality, makes a durable floor, and is preferable to the finer grained woods in wet places, as it does not swell and warp so badly. It is less durable, however, and therefore not recommended for the greatest permanence in rooms such as class and lecture rooms. Maple, birch and beech all make good floor material. These are usually laid in strips ⅞ in. thick by 2¼ inches wide.

Annual Report for the Municipality of South Vancouver

The annual report of the municipality of South Vancouver, on the work carried out under the Board of Works (S. B. Bennett, municipal engineer) has just been presented.

Street Improvements

The following summary represents the work done on street improvements in 1915:—

	Lineal Feet	Miles
Streets cleared and rough graded	2,230	.422
Lanes cleared and rough graded	4,180	.791
Streets graded	7,430	1.407
Lanes graded	740	.141
Streets macadamized	9,710	1.839
Streets planked	2,270	.430
Lanes planked	.150	.028
Planking removed	3,600	.681
Bulkhead in place	1,040	.197
Three-plank walks	400	.076
Box drains laid	842	.500
Rock broken ... cu. yds.	3,316	

Waterworks

The waterworks department reports operations during the year and the cost as follows:—

Construction		
12-in. Mains	3,853 ft.	
8-in. Mains	1,110 ft.	
6-in. Mains	4,815 ft.	
4-in. Mains	1,130 ft.	
Temp. Mains	5,255 ft.	
Hydrants	25	
		$18,964.16
Services (including all transferred)	120	1,271.36
Meters (including all transferred)		282.39
Operating		9,966.00
Maintenance		7,449.41
Lowering Mains		1,444.61
Total		$39,377.93

Sewers

The work carried out under the sewer committee for the year ending 1915 is summarized as follows:—

Manitoba Street outfall	2.865 miles pipe laid
George Street outfall	1.888 miles pipe laid
Glen Drive outfall	.082 miles pipe laid
Total	4.835 or over 4¾ miles
Concrete manholes completed	74
Concrete lampholes completed	16
Sewer permits issued	158
Connections to houses, completed	94
Stand pipes put in place	22

Quantity Surveyors

Our recent remarks re quantity surveyors have occasioned some surprise in England where they have been noted by engineering journals in their editorial columns. The Surveyor has the following:—

"The special function of the quantity surveyor in British architectural practice is so well defined, and its utility is so well recognized, that it is rather surprising to learn from a recent issue of the Contract Record of Toronto that the term 'quantity surveyor' is a new one in Canada. The arrival at Winnipeg of Mr. Hugh Watkins, the well-known London quantity surveyor, who is acting professionally in connection with the erection of the new Parliament buildings, is apparently so much of a novelty as to merit special comment. The present practice in Canada, even in the case of buildings of first-class importance, is for each contractor who intends to submit a tender to prepare his own quantities from the drawings and specifications received from the architect. The absurdity of duplicating work in this way, and the greatly increased chance of error arising from the impossibility of a contractor's estimating clerk exercising the care and skill of a professional surveyor are manifest; and Mr. Watkins believes that in the near future the British practice will become general throughout the Dominion. Commenting generally on the subject, our contemporary points out that under the old system, if twenty contractors tender for a given work, nineteen useless bills of quantities are prepared, all of which have to be paid for by someone in the long run in the form of increased establishment charges in the contractor's business. Moreover, a full bill of quantities prepared by an independent surveyor has a further advantage for all parties, in that it forms a reliable basis upon which extras and deductions can be calculated."

And this from the Building News:

"We are glad to note that Mr. Hugh Watkins, quantity surveyor, of London, has arrived in Winnipeg, and that he and his two assistants have commenced their duties in connection with the New Parliament Buildings, which are being erected from the designs of Mr. F. W. Simon, F.R.I.B.A. Quantity Surveyors hitherto have been unknown in Canada, but a strong movement is on foot to insist on their employment, as in this coutnry, for all buildings of any importance. Under the existing system in Canada an architect is engaged to prepare the necessary drawings and specifications, which are forwarded to each contractor who has signified his intention of tendering for the work. Each contractor then sets to work to prepare the necessary measurements of materials and labor to enable him to arrive at the amount of his tender. This does not apply to buildings alone. At the present moment a Canadian city is calling for tenders for a gravity filtration plant—plans and specifications to be furnished by the contractor. Thus, assuming twenty contractors tender for a job, nineteen sets of quantities are useless and waste labor. One result, of course, is that careful and accurate estimates are rare, and another that no reliable basis exists on which any extras or deductions can be arrived at."

The big obstacle, as we see it in Canada, to the more general employment of a quantity estimator, is in placing the responsibility in case of an error in estimating. The contractor plainly should not bear the added expense, the estimator probably could not and so it must fall on the shoulders of the owner.

If outstanding contracts are filled, and the war continues throughout 1916, it seems clear that during 1915 and 1916 there will have been spent in Canada for war supplies considerably more than $500,000,000.—Sir Edmund Walker, at annual meeting Bank of Commerce.

"On Doing Your Bit"

By Bill

The war is slowly but steadily pushing on, month after month passes by and no decisive victory has at present been achieved, but we are full of optimism, for lots of young fellows we know are "doing their bit" and doing it well.

It may be a somewhat pertinent question but just put it to yourself now. "Am I doing my bit" and if not, why not?

There are some amongst us too old, too short winded, and others too apathetic to do their share in this gigantic struggle.

The single young fellow whether he be rodman, instrument man, or assistant engineer is missing the opportunity of his life, if he is not now in khaki.

The young Canadian is as anxious to show his loyalty as the Australian or New Zealander, and we must all be prepared to make any sacrifice to do our duty for our king and Country.

But look again, just think of the experience to be gained. The young Canuck on his return would be able to talk of the wonders of the Old Country, of France and Belgium and possibly of having shared in that greatest of all honours, viz., the entry of the Allies in Berlin. Then a little later when he may be discussing pavements, boulevards, street lighting, &c., he would be able to turn to his committee saying, "You know when I was in Paris I inspected the Rue de Joffre; it is paved with wood blocks on concrete base and is in excellent condition," or, "In Antwerp I noticed that the pavements were not so good as in London." While the younger members of the staff would simply gaze with wonderment and admiration at the man who could discuss with such ease the geological formation of France, Flanders or the Dardanelles.

The King's medal with bars and ribbons and, possibly, a D. S. O., would cause the directors of the company or corporation to tread lightly and with reverence as they approached his drafting table, and the very fact of being able to say "In my younger days when I was with my friend French," or "In my last interview with Kitchener," would make the most autocratic councillor turn green with envy.

Bishop Strachan School, Toronto

New Residential School for Girls on College Heights—Collegiate Gothic Style—Carefully Designed to Meet Modern Educational Needs

AFTER a long and honorable career in the buildings now so familiar to present and former pupils it was decided several years ago to move the Bishop Strachan School to another site farther north, where modern buildings, large enough to accommodate the ever-increasing number of pupils, might be erected. Accordingly the council acquired a most suitable and beautiful location on College Heights. The new site comprises a whole block of a little over seven acres, bounded by Lonsdale Road and Russell Hill Road on the south and west and by Frybrook Avenue and Warren Road on the north and east. On this new site has been erected a handsome building, carefully designed to meet modern educational needs, and to furnish the most complete equipment in every department.

The structure is built of grey Credit Valley stone and the architecture is in the Collegiate Gothic style. The school and residence form two sides of a quadrangle, connected at one end by the Assembly Hall and at the other end by a wing including a double row of music rooms and domestic serving apartments.

The general plan of the building has the great advantage of securing a double south aspect, by the use of the quadrangle in the centre of the building. The main south facade on Lonsdale Road has a length of 285 feet and the west front on Russell Hill Road a length of 240 feet.

The north wing, or residence, and the west wing are four stories high, while the south wing or school building is three stories, exclusive of the basement.

On the east side of the quadrangle is a large Assembly Hall 32 ft. 6 in. by 87 ft. 7½ in. and approximately 30 ft. high, with a seating capacity of 400 persons, and with a platform space of 33 ft. 6 in. by 14 ft. 6 in.

Basement

The basement plan, while not totally excavated to the size of the first floor plan, contains junior and senior cloak rooms and toilet rooms under the east and south wings. The west wing is given over to the domestic apartments necessary to carry on such an institution, and in the northwest corner is a large gymnasium. The domestic service equipment includes kitchen, bakery, dairy, laundry, fruit, vegetable and meat departments, etc. A large dining room for the servants is provided in the southwest corner. The gymnasium in the northwest corner is 69 ft. 6 in. by 24 ft. 6½ in. A swimming pool, 28 ft. by 13 ft., is provided, with showers and dressing rooms situated in the north wing.

First Floor

In the south wing on the first floor is the principal's office with a waiting room to the right of the main hall and a staff common room to the left. Across the corridor, running at right angles to this hall, are class rooms, see plan herewith. In the west wing are modern laboratories for the classes on domestic science, the junior dining room, the servery and the main dining room which is directly over and similar in floor plan to the gymnasium below. Food is prepared in the basement and elevated to the servery by a dumb waiter and served from here to both dining rooms. In the north wing are two large dormitories and two spacious study rooms in which the students may spend their spare time or study hours. The east wing is mainly taken up with the Great Hall, or Assembly Room.

An important feature of the building is the number of piano practice or music rooms; there are fifteen on the first floor on the east and west sides of the

Bishop Strachan School, west front and south facade, showing main entrance.

quadrangle and eight on the second floor on the west side of the quadrangle. In the construction of these rooms every known device for deadening sound has been employed.

Second Floor

The second floor plan is taken up entirely by dormitories in the west and north or residence wings with class rooms in the school wing. Directly over the main entrance on the south is a spacious library. The science laboratories are on this floor in the southwest corner.

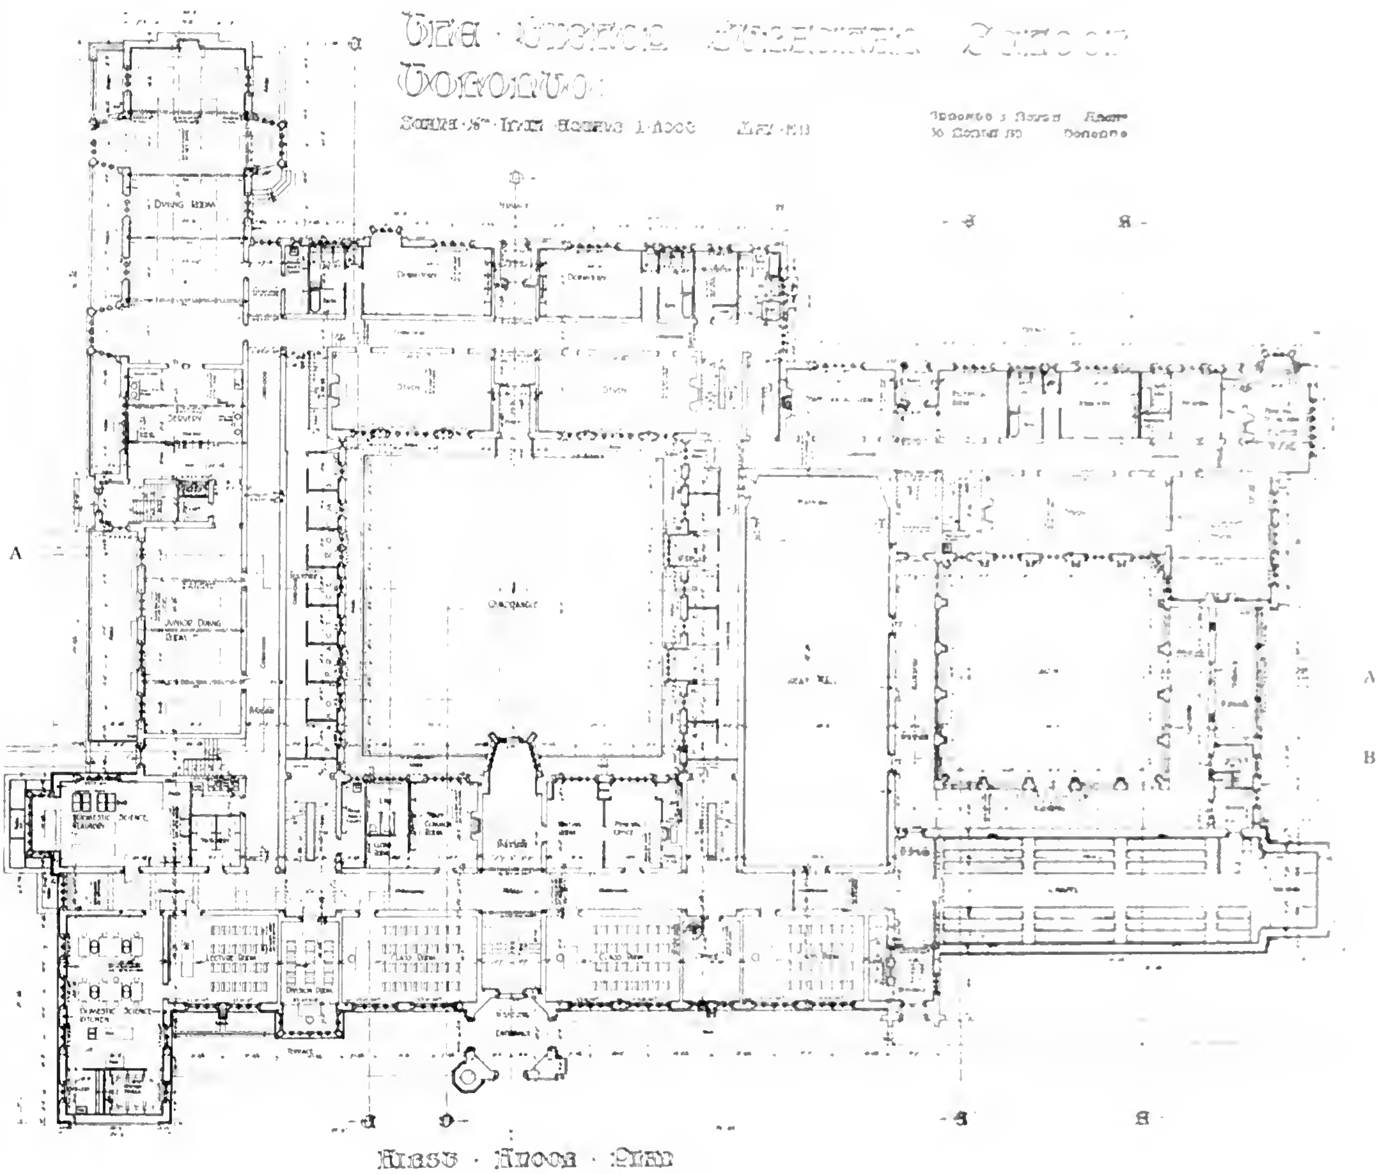
Third Floor

The third, or top floor, plan of the school wing is taken up by studios fitted with skylights and good northern light for art purposes.

The fourth, or top floor, plan of the north, or residence, wing is given over entirely to bedrooms.

Equipment

The buildings are heated by the most modern hot-water system, in which the water is pumped through the pipes by turbine pumps; ensuring perfect circulation. The water returns to the pumps with only 3 degrees loss in temperature in passing through a half-mile of pipes. For hygienic reasons this system was preferred to steam heating, as the heat given off from hot water radiators is of lower temperature and does not deplete the air of its natural humidity. The heating plant is in a separate underground building to the northwest, the water being brought to the school by an underground tunnel, a plan which makes for both safety and comfort.



Layout of first floor plan Bishop Strachan School, Toronto.

In the construction of the building every care has been taken to guard against danger of fire. The building is constructed of grey sandstone, with copings, facings, cornices and window casements of finished cut stone; leaded glass and steel sashes are used throughout the building.

The floors for the most part are 7/8 in. beech, laid on strips on 7/8 in. rough flooring. In the basement, corridors, toilet rooms, etc., 1/2 in. granolithic finish on 4 in. of concrete is employed. The interior finish is dark stained oak with seats, desks and other interior furnishings to match. The main roof of the building is felt and gravel, with green slate shingles on eave slopes.

A notable feature in the building construction is the lighting. Special attention has been paid to the

Art Studio—Bishop Strachan School.

lighting of the rooms, both by day and night; this is at once evident by the great number of windows, which are large and well placed so that the rooms enjoy a generous flood of sunlight during the day.

The ventilating has also been given a great deal of consideration, necessary on a building of this kind, and has been worked out to ensure an adequate supply of fresh air at all times. A further special feature is a refrigerating plant, installed so that the school may have cool rooms to properly care for its food. They manufacture their own ice, thereby eliminating any danger of diseases from the use of impure ice. In all these matters the health and comfort of the pupils has been the first consideration and no expense has been spared to secure the best results. The building, which is now occupied, was designed by Sproatt and Rolph, architects, and was built by the following sub-contractors: masonry, Page & Co.; carpentry, A. Weller & Co., Ltd.; heating, W. J. McGuire, Ltd.; wiring, Bennett & Wright; electric fixtures, R. A. L. Gray; steel sash, Henry Hope & Son; painting, Faircloth Co., Ltd.; roofing, Duthie & Son; interior furnishings, Murray-Kay, Ltd.; kitchen equipment, Geo. Sparrow & Co.

The Imperial Munitions Board have given orders in Canada for 22,800,000 shells, having a value of $282,000,000. If we add to this the orders for cartridge cases, primers, forgings, friction tubes, etc., a total of $303,000,000 is reached. —Sir Edmund Walker, at annual meeting of Bank of Commerce.

Assembly Hall—Capacity 400 persons.

System Applied to Street Management

Applying a scientific, systematic business plan to street and road improvements, repairs and maintenance—Making it a business organization

By W. P. Blair*

STATE highway departments, collegiate institutions, and even the office of Public Roads of the United States, have deemed it advisable to construct various types of roads, and roads of like type, of somewhat different construction, with a view of study, recording data, watching behavior, keeping a correct cost, maintenance and repair charge, comparing wear and tear in an endeavor to reach some conclusion and gather some testimony as to the worth and value of such roads respectively. This endeavor on the part of these organizations is perhaps an effort as nearly practical as possible under existing circumstances. Still, in every effort of this sort one's conclusions are drawn but from one character of travel. It is necessarily alike over the various sections. No law of averages can be applied and the best results reached after years of study are of doubtful character. The conclusions are reached from conditions that are widely different from those actually existing on our streets as a whole, no one of which bears the same travel. The effort itself largely artificial, does suggest however, that no actual condition has been put to any practical purpose from which correct conclusions might be reached. And it does strongly suggest that the information sought is of great necessity.

Why cannot information of this character be obtained in a more practical and scientific manner and the information itself afford greater reliability and more adequately meet the necessities of the case.

There is no plan of street and road management or street administration that can be called fundamentally efficient for the reason that no plan management exists that includes in the construction, maintenance and repair, the availability of the information sought by the building of those so called experimental roads.

Streets which are improved are of various types.

They are in various states of repair.

They are of various locations.

Even a single street receives a variety of travel.

Single streets are often of such location that sections receive more or less travel.

The streets overlie varied conditions of soil.

Some streets must receive artificial drainage.

Influence of Promotors

The choice, the character, the type, the cost of all, are subject to a greater, or less extent to the whim, the notion, to the cheapness of cost, influence of zealous promoters, sometimes secured by one neighbor selling out another—in almost every case chosen from any consideration other than the ones upon which good sound judgment should be exercised. These streets representing one great mass of unknown conditions, evidence simply a lavish expenditure of money known to us as the streets of this city or that—roads of this county or that.

But few of these streets and roads have a legal name, most of them bear merely a nick name. None of them bear any identification whatever or relationship to commercial accounting such as is found in every well regulated commercial establishment. The original investment as to its part or its whole is not of record—is not charged; cost of up-keep is so confused with general charges against the whole lot that no knowledge whatever is obtainable as to the amount expended on any street or road, and we do not even know the actual reason for the expenditure, whether it was on account of repair due wear and tear, on account of some defect of original construction, on account of accident, on account of some cut and opening, nor does any record disclose whether the street or road has remained out of repair or whether repair was needed, or whether the street or road has cost in repair an amount exceeding any justification for maintaining a road wholly inadequate for the travel and traffic that passes over it.

This chaotic and inexcusable street and road mismanagement has been allowed existence because streets and roads are sustained by donation in some one form or another, their earning capacity is not held to account. In a commercial establishment, if a like manner and method of conducting was permitted, the institution would soon fall into bankruptcy. A department, a machine under such loose methods would continue in operation at a loss and escape detection. No information as to the value, the worth and economy of any tool or apparatus would be possible upon which improvements could be suggested and undertaken.

Street Management

What business plan is there, therefore, of street and road management that could be put into operation which would serve immediate and emergency needs equal to any plan now in existence, and at the same time furnish such accurate information as to original cost, cost of operation and services, usually designated as maintenance and repair, the application of such supervisory oversight as that when a break occurs it could at once be determined whether or not it was due to wear or tear or an original defect in some part. Dealing systematically with cuts and openings and replacements to effectually regulate to the greatest advantage of the street, that annoying privilege.

Separate these streets in certain divisions and those divisions into sections, of in no case exceeding one mile in length. These sections must be measured, numbered, and recorded for the purpose of complete identification. To illustrate: East 45th street, division number 9, section 17, beginning at the north property line of Superior and ending with the south line of St. Clair, including intersections therein, 4,800 feet in length.

You can then treat that particular section of street as a thing, a piece, as a machine from which you can extract information, of every kind and character. Similar information can be gathered in like manner from every street within the corporate limits of the city. With the information in hand, which is possible to gather under such a plan, the adaptation of streets of type and kind for the varied services, in a

*Presented before Section D of the American Association for the Advancement of Science at the Columbus meeting December 29, 1915.

short time will become apparent not only to the student applying a refined study to the situation, but to the layman as well.

Every county should be required by law to establish a complete identification of roads within the county by section number, of lengths not exceeding two miles, and location by township, and such identification should be made of record and in all cases of contract, maintenance and repair, expenditure therefor should be made and charged as against the particular section upon which the expenditure was made. By such a plan of road and street management, the greatest possible economy would at once become apparent by the ability to trace the actual dollar to the thing purchased for the particular road. Aside from this benefit, data, experience and comparison would become available for future judgment. Street and road improvements, maintenance and repair would at once become a scientific, systematic, business like operation and wasted millions would be saved.

High Level Bridge at Cleveland, Ohio

591 ft. three-hinged arch span holds third place in span length in America—Relatively simple and inexpensive erection devices used

Satisfactory progress was made in the erection of the new Detroit-Superior high-level bridge at Cleveland during the past season by the use of relatively simple and inexpensive erection devices. The 591-ft. three-hinged arch span, now completed, holds third place in span length in this country, being exceeded only by the Hell Gate arch and the Niagara arch. The steel for the arch span was erected between July 29 and Nov. 5, including the placing of the double-deck floor.

The closure of the main arch was made on October 8, using screw toggles in the back-stays for adjustment, in a manner similar to the closure operations for the Hell Gate arch, with telephone communication. The essential difference in the two operations was in the use of toggles for adjustment of the Cleveland structure and screw jacks upon the vertical posts of the backstays in the Hell Gate arch. Cantilever erection using backstays was the fundamental method in each case, but the Detroit-Superior arch erection was started at each end from a high tower on which the traveler was assembled, and the backstays could be carried to the next adjacent pier to develop the uplift.

Steel Erection Towers

At each end of the main arch span, just behind the abutment piers, a 90-ft. steel tower was first erected by means of a 115-ft. ginpole. This ginpole was used from the ground to erect the lower section of the tower, then raised to the level of the pier and supported on the tower section already erected, and finally raised another panel for the purpose of erecting the top-chord traveler and two stiffleg derricks.

On top of the erection tower, shown in one of the photographs, is a beam runway for the traveler frame, which cantilevers over the tower. The horizontal steel struts are part of the tower, as can be seen in the photograph. They transmit the component from the anchorage at the adjacent pier to the main pier, thus eliminating any horizontal thrust due to cantilever erection. The maximum stress in each backstay, including wind, was 2,230,000 lb., and the area was 143 sq. in. The backstay consists of a line of eyebars supported by the tower and containing the framed toggle arrangement clearly shown in one of the views.

The toggle was designed to put the adjusting screws in tension, and these screws were turned by a shaft connecting them, as shown, in order to insure uniform movement of both arches. The power for turning was obtained from a single-drum hoisting engine on the ground below, connected to a sheave wheel on the center of the shaft. One turn of the toggle screw at the beginning was computed to cause a vertical downward movement at the crown of the arch of $2\frac{3}{8}$ in., and thirteen turns of the shaft were re-

* Engineering Record

quired for one turn of the screw. The total stress in the eyebars at the toggle was 2,530,000 lb. including wind, and the maximum component carried by the screw was 517,000 lb. tension. The screw is 9¾ in. in diameter, with 1¾ in. pitch.

The top-chord traveler was a timber framework consisting essentially of 12 x 12-in. horizontal chords with 4 x 12-in. bracing, and two transverse struts of braced timbers. In order to allow for the changing slope of the top-chord runway and keep the lower sills of the derrick horizontal, adjustment was pro-

Fig. 3—Top chord Travellers lift steel from scows during erection of Cantilever.

vided by a line of holes in the two 15-in. channels to which the built-up shoe at the rear of the derrick was bolted. Two 25-ton stiffleg derricks were mounted on the frame, the transverse legs being spliced at their intersection.

Erection Progress and Closure

The erection of the steel arch was begun on the east side July 29, and on the west side August 26. The delay on the west side was due to awaiting the completion of the main pier, and the erection progress was fixed by the west cantilever. The travelers were supported on the steel I-beam stringers of the span, temporarily used on timber bents above the top chord for the first four panels, as seen in the photograph. In beginning the erection of the end panel, the end lower chord, which is the heaviest member in the bridge and weighs 30 tons, could not be handled by the derricks without special equipment. As connection of the backstay to the end of the chord could not be made until the panel was erected, falsework bents were used for the end panels. A pair of sheerlegs on the face of the pier, with tackle attachment, made it possible to use the derricks for hoisting the end chord.

The actual working time on the west side for erecting the arches and bracing was 32 days of 8 hr. each. In this time about 1,250 tons of steel was placed on the west half. All truss members up to the four center panels, except the bottom chords, were riveted up, the other joints being bolted until after closure.

Closure—Special Erection Struts

The closure of the arch was successfully accomplished October 8. The two halves of the arch lined up within ⅛ in., easily adjusted by a cable, and were within 22 in. of bearing when the lowering operation was begun about 10.30 a.m. By 2.23 in the afternoon, with a 2-hr. intermission, the arch closure was completed. Telephones were used at each hoisting engine turning the toggle screws, and at the centre where the superintendent of the erection company controlled the operation. A total vertical motion at the center of about 22½ in. brought the arch to a bearing.

Owing to the fact that the adjacent concrete arch spans cannot be placed until after the main steel arch span is erected and the backstays and towers are removed, the main abutment piers are subjected to excess unbalanced thrust until these arches are in place. To provide for this thrust two concrete struts 5 x 7 ft. in section were placed between the bases of the abutment pier and the adjacent pier where the next arch had been placed and was thus available for resistance.

Erection of Floor

The double-deck floor system, with six trolley tracks on the lower level and a highway floor and sidewalks on the upper level, was erected from the center toward the ends by the travelers on the top chords. As in the case of the main arches, the material was hoisted from scows in the river. It was placed by the following sequence of operations: First, the 8 x 1⅜-in. nickel-steel hangers were placed in the arch chord, then the pin-connected floorbeams of the upper level and the builtup hangers for the lower level were erected. The lower-level floorbeams were then placed and the riveted connections to the hangers made. Stringers and bracing could then be erected.

By November 5 all steel, about 4,200 tons, had been placed. Nickel steel was used for the main members and carbon steel for the bracing and floor system. The concrete arches of the approaches are all placed except the two adjacent to the main arch.

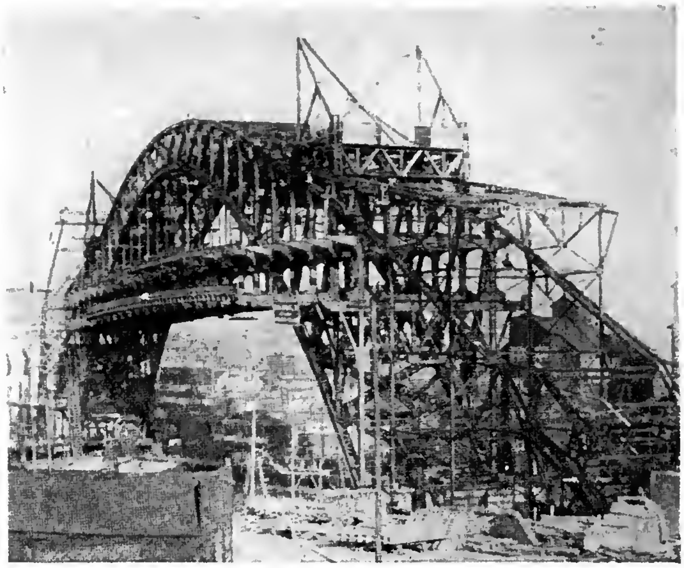

Fig. 4—Archclosed and double-deck floor steel placed by returning Travellers.

The west approach is now completed, and also the lower decks on many of the spans of the east approach.

The contractor for the fabrication and erection of the steel arch was the King Bridge Company, Harry Fuller, chief engineer, was in charge of the design and construction of the erection material.

Fuller Details in Specifications

The duty of the Engineer or Architect to supply adequate details of existing conditions—A complete list of quantities, with a schedule of unit prices

By Owen W. Smith, C.E., Mem. C.S.C.E.*

Much has been said, written and spoken about plans of structures, with all their accompanying detail, but little has been said or discussed about specifications, which all know go hand in hand with all plans, and in contract work is one of the written documents of the contract ranking next in importance to the plans. This paper will not attempt to describe in great detail what is necessary to make a specification complete and full on every point to be covered in various classes of work. The intention is rather to discuss and comment on the general principles of specifications as they have been handed down to us by our predecessors, in this line of endeavor, and as they are written and enforced in our own day.

Specifications solely for materials, or processes, and not prepared strictly for use in a contract do not present the same problems that arise when the specifications are part of a contract document.

Nor are they so important in certain types of contract such as the cost, plus a fixed sum, or cost plus a percentage contract, as changes in the class or style of work can be much more easily made without making the changes a point of dispute between the Engineer and the Contractor.

But in the ordinary class of straight contract, in which the parties are bound within definite and prescribed lines, too much care cannot be taken in drafting the specification which becomes a vital part of the contract.

Under the unsecured cost contract they are of more vital importance to success than under the secured cost contracts for the reason that when a man is paid the cost plus a profit for all work it matters little to him what he may be required to do or how he must do it; when, however, he is asked to name a sum of money for which he is willing to do certain work, he must know accurately what he will be required to do for the money, otherwise the sum he may name will be like a gambler's guess rather than an accurate estimate.

Primarily specifications are drafted so that in conjunction with plans certain works may be built, the objects in view being that the work will fulfil the duty for which it is designed, will be accomplished for a certain, sum, and will be completed within a certain time.

Duties of Specifications

The chief duties of the specification are these: to define or describe the work so that any competent contractor may submit an intelligent bid, and to establish a guide and a standard by which the contract may be interpreted with fairness to each party.

To attain the first of these desired results, great attention should be given to accurately and clearly describe what is desired to be done and the existing conditions under which it is to be constructed.

A complete specification, in conjunction with the plans should indicate clearly, concisely and accurately all the details of the structure; the class of materials to be used, what is to be supplied by the contractor, and by the corporation, and in the case of corporation supplies, where these are to be delivered. Also the local conditions, such as the conditions of the substrata on which foundations are to be placed, flood conditions, where they affect the work, should be fully described, and any other matter which might affect an intelligent bid one way or another.

It is not sufficient that the engineer should merely indicate by the plans and specifications the type and character of the structure to be built. Usually he has a great many advantages in planning an enterprise over those enjoyed by the contractor. Generally he is not limited in the time taken in drawing his plans and drafting his specifications, and has, or should have, ample time to investigate all conditions and make researches prior to the time when bids are called. No structure or work should be designed without a full knowledge of local conditions.

We often find, however, that the bidder is not given any information about local conditions, even when it is in the possession of the designer and he is left to shift for himself and get, as well as he can, the information which has a most important bearing on the ultimate cost of the work.

Time to Tender Often Short

The time allotted to the contractor is often too short to admit of anything but a brief survey of conditions, and he has to practically guess about conditions, which are of vital importance to all concerned. Hence we often find, as a result of lack of this information, a great range in the amounts bid, a wiser and sadder contractor, and a worried and disgusted engineer. Further, it is the duty of engineers or writers of specifications, to provide positive information of local conditions pertaining to the work, above ground and below.

Is it not sufficient to ask bidders to spend their time and money in obtaining that information which is solely within the province of the contractor, and supplying the required security, without putting them to the necessity of gathering data, which is within the province of the engineer to do so?

In this connection the point of view of many engineers appears to be that they confer a favor in handing plans and specifications to a contractor for bidding purposes. Money deposits are often required before these can be obtained and frequently they are not permitted to take them from the office, and requests to have them sent by mail are refused. It is hard to see how the contractor is under any obligation in an effort to bid on work, as these efforts will require both time and money to accomplish, and with every prospect, on the average, of the contractor being out of pocket.

Viewed from a business standpoint, competition is the life of trade, in these matters as in others, and the engineer's duty to his employers or client would be to facilitate in every way the interest of all prospective competent bidders.

Under this heading it will be proper to discuss briefly the actual wording of specifications before passing on to the next phase.

Clearness, brevity and consistency are the three

* Before Regina Branch C.S.C.E.

things to be attained in the wording of a specification. Lengthy sentences of necessity become involved, and reiteration of descriptions of similar works and materials does not add strength to the document. Tautology is to be avoided if possible. Words such as "proper" and "sufficient" being indefinite have little meaning, and the writer should avoid them by stating clearly what is proper and sufficient.

Stock clauses, or standard specifications to apply to different classes of work, or different works of the same class, are dangerous, and may lead to serious trouble between all parties concerned.

Clearness, Brevity and Consistency

To sum the matter up; if the specification drafter clearly understands what he is writing about, says exactly what he means, and not a word more, clearness, brevity and consistency will be attained.

Now in regard to the second requirement which has been laid down as a basis, namely, to establish a guide and a standard by which the contract may be interpreted with fairness to each party. Several things are essential to accomplish this, such as;—

(1) A complete list of quantities of all work.

(2) A schedule of unit prices of all items in the work. This of course would mean a unit price bid which can easily be figured to a lump sum if desired.

(3) And in addition a schedule of prices for extra work.

Bidders should not be required to estimate their own quantities. The bidder, while perfectly competent to construct the work, may not be expert in calculating quantities and, in the limited time usually at his disposal, should not be required to spend time on these details, which would be more profitably spent on matters essential to intelligent bidding, such as the labor problem, materials, insurance and the hundred and one things which must be foreseen in actual successful construction work. A definite list of quantities provides a basis of working which not only aids the bidder in estimating closely, but gives him confidence in the engineers who are to direct the work, and frees him from that haunting suspicion that perhaps in haste he has omitted something; or else he may estimate too largely making his bid appear absurdly high.

A schedule of unit prices for extra work which might be encountered will eliminate, in a large measure, force account work and such items which often become a bone of contention between contractor and engineer.

(4) All items in the schedule of prices should be adequately covered by a corresponding clause or section on the specification.

The difficulty of obtaining fully detailed information of what is really wanted when bidding on work is one of the serious problems which often confront the contractor, for it is largely the details which determine what work is really worth.

The more doubtful therefore the bidder is as to what may be required of him, the greater sum he will add to his price for contingencies which may arise. This will be particularly so if the engineer bears a reputation for narrow-mindedness and arrogance.

The gist of the matter up to this point is to give all the necessary information in a specification, whether it be description of work and material, local conditions, quantities, matters of extra work, etc., and to have it properly expressed so that all bidders may precisely and explicitly know what is required of them.

Penalty Clause

It is well known that time penalty clauses are not often enforced in a contract, and the general opinion largely prevails among construction men that they are of little effect. One of the chief reasons for these conditions is that usually the owner, corporation or engineer is unable to keep their part of the contract exactly on time, and there is always an avenue of escape opened for the contractor.

It is conceivable that in some construction work there is an absolute need of it being finished by a certain time, and in such cases the penalty clause may have some legitimate use, but in the usual construction contract its principal effect would be to raise the amount bid by tenderers who have fears of its application.

It can be laid down as a rule that the competent contractor is most anxious to finish the job as rapidly as is consistent with efficiency. Construction work in common with many other operations has an efficient and economical rate of progress. To exceed this means increased cost and therefore, if possible, specifications should state a reasonable time for the completion of the contract, giving due consideration to unforeseen difficulties and contingencies which may be encountered in the work, and also in the customary local conditions appertaining to the work.

The time penalty clause should be used only in exceptional cases where it is an absolute necessity to complete within a certain time. The careful bidder will then make due provision for the same in his tender. It seems ridiculous to have, for example, a fifty dollar per day, time penalty clause placed indiscriminately in all contract specifications, when in nearly all cases the contract will be carried out along the usual lines of making speed as rapidly as circumstances permit.

Business Relations

Specifications are usually divided into two divisions, the first, with which the foregoing remarks have been dealing, viz. the clauses relating to the description of the work whose accomplishment is the object of the contract, called "Specific Clauses".

The second division relating to the rights, duties and obligations of the contracting parties, and the engineer or owner. These might be called the business relations. In this country they are generally classified as "General Clauses".

During the process of developing specifications it would appear that the general clauses have received more cultivation than the specific clauses.

Many of these latter clauses (sometimes known as "The Big Stick" clauses) are manifestly unfair, illegal and injurious to the engineering profession.

Inspector's Powers

The clauses governing the inspector's power are also usually contradictory, for example: An inspector shall be appointed by the corporation and the contractor obey without question his order and instructions, but no approval of the inspector shall be taken as an acceptance of improper work or material which must in every case be removed and promptly replaced when discovered.

The inspector has power to order defective work or materials but has no power to accept same. Surely an unfair condition to impose.

(Concluded on page 61)

The Disposal of Sewage by Dilution

A bio-chemical method of purification—Effect of normal sewage on streams—Much depends on the amount of oxygen dissolved in water (concluded)

By W. E. Adeney, D.Sc., F.I.C.

In order fully to appreciate the very serious injury which sewage or other refuse solid organic materials are capable of causing in a stream, it is necessary to understand the wide difference of their behaviour towards the dissolved oxygen of any water through which they become dispersed when (1) in the fresh condition, and (2) after undergoing bacterial fermentation under anaerobic conditions when deposited for any length of time along the bed or banks of a stream.

Sewage or refuse solids in the fresh condition, like fresh sewage liquor, when dispersed through large volumes of "clean" water, do not directly combine with the dissolved oxygen, but are only induced to do so indirectly and gradually under the influence of any water bacteria that may feed upon them.

When, however, the same solids, after remaining deposited on the bed of the stream for any length of time, and undergoing anaerobic fermentation, become dispersed through "clean" water, the sulphides and deoxygenated organic bodies now mixed with them will directly combine with the dissolved oxygen immediately they come in contact with it. So that, while the waters of a "clean" stream may transport sewage or other refuse organic solids in the fresh condition, and may carry them for several hours without suffering any appreciable reduction in their dissolved oxygen content, the same solids, after remaining deposited along the bed and banks of a stream, and there undergoing anaerobic fermentation, will, when disturbed and dispersed through a like body of "clean" water, immediately absorb the dissolved oxygen of the water by direct chemical combination with it.

Injury to Rivers

Many of our rivers in this country suffer more or less serious injury from sewage solids in the manner here described. The writer has had opportunities of carefully investigating the condition and circumstances of several of such rivers, and he has given detailed description of some typical examples in the Appendix VI. to the Fifth Report of the Sewage Commission. Reference may also be made in this connection to the 1912 report of the Metropolitan Sewerage Commission of New York, and also to the 1914 report of the same commission.

It will suffice to give here, by way of illustration, one typical example: The Yorkshire river Ouse for a great part of its course is a fairly clean, natural stream. In spite of some rather considerable pollution by the sewage of towns and villages, there is nothing in its waters to prevent or destroy fish life. But near Goole, where it is joined by the Aire and Don, it becomes at times seriously polluted by putrescent sewage solids brought down to it by these tributaries during freshets. It is a matter of yearly complaint that the gross pollution of the upper reaches of these streams occasionally poison and deoxygenate the waters of the Ouse, and prevents the passage of salmon trying to ascend it from the Humber.

Both the Aire and the Don, between their most polluted reaches and their junctions with the Ouse, flow through courses of considerable length, and along which they receive little further pollution, and in which the bio-chemical oxidation of liquid sewage organic matters that had become mixed with their waters is very considerably advanced.

But both tributaries, it must be remembered, are very grossly polluted along their higher reaches. Thus the Aire, with its nearly equal effluent the Calder, drain an area within which lie the towns of Bradford, Leeds, Huddersfield and Wakefield, and villages in which the woollen trade of the West Riding of Yorkshire is carried on.

During dry weather crude sewage solids are deposited along the beds and banks of the upper reaches of these rivers, but the liquid portions gradually undergo fermentation as they are borne along by the waters of the rivers, and the writer has found that, by the time they reach the Ouse in dry weather, practically the whole of the dissolved sewage organic substances originally present becomes completely fermented, and that the second stage of fermentation—that is, the bio-chemical oxidation of the ammonium compounds, has been well established.

But during freshets the sewage solids which had accumulated in dry weather in these rivers, and had meanwhile become putrescent, are washed down into the Ouse, and absorb the dissolved oxygen of its waters, so that the waters are rendered incapable of supporting salmon and other fish life.

These solids also become deposited along the banks of this part of the Ouse and temporarily discolor it. The banks of the river are steep and uncovered at low water. They are overlaid with clay and fine sand, which, as just stated, becomes discolored after freshets, but appears of a clean yellow color during dry weather. A good deal of this solid polluting matter, however, remains imbedded in the clay below its surface, and causes further injury to the waters of the river, as will appear from the descriptions that follow.

The Ouse and its tributaries the Aire and the Don are influenced by tides for considerable distances above Goole. The rate of flow and ebb in this portion of the river Ouse varies very greatly during spring and flood tides. At spring tides the flood lasts about 2 1-4 hours, with an ebb of 9 1-4 hours, and a period of quiescence of about half an hour at high and low water. At neap tides the flood lasts for four hours, and the ebb for 7 1-2 hours.

At spring tides the river Goole rises from 16 ft. to 20 ft., while at neap tides the rise varies between 10 ft and 13 ft.

The great and rapid rise of the river during spring tides must obviously produce a strong scouring action on the banks of the river, and a much stronger action than at neap tides, when the river rises more slowly and to a less height.

Tidal Investigations

Dr. Maclean Wilson has published some valuable and instructive results of some careful investigations that he has made on this portion of the river Ouse during spring and neap tides, and his chemical analyses show that the suspended matters carried by the waters of the river is very much greater during spring tides than during neap tides—the maximum range being 1,100 parts suspended matter at spring tides to 75 parts per 100,000 parts of water during neap tides.

Notwithstanding the fact that the liquid sewage matter in the river is diluted with very much larger volumes of clean water at spring tides than at neap tides, the dissolved oxygen content of the river waters during spring tides is nevertheless considerably less than at neap tides. The only possible explanation for this apparently anomalous state of things is that the clay and sand which are disturbed by the tidal currents in this portion of the river contain putrescent sewage solid matters, and that these matters are more effectually scoured and dispersed in larger quantities through the tidal waters by the spring tidal currents than by the neap tidal currents, and that these putrefactive matters rapidly absorb dissolved oxygen from the tidal waters as they become dispersed through them.

As regards the possibility of liquid sewage matters contributing to an appreciable extent to the exceptional deficiency in the dissolved oxygen content of the spring tide waters of the river, several reasons may be advanced to show that this is impossible. For example, Dr. Maclean Wilson's analytical figures show that the proportions of liquid sewage matters in the spring tide samples are about ten times less than those in the neap tide samples, and that, nevertheless, they show a greater deficiency in dissolved oxygen. Some of the spring tide samples were so slightly polluted by liquid sewage matter that they contained no ammonia, and yet, notwithstanding this, their dissolved oxygen content had been so greatly reduced that they were no longer able to support salmon and other fish life; while the neap tide samples, though they contained very decided quantities of ammonia, indicating distinct pollution with liquid sewage matter, their oxygen content was not so largely reduced. It was, in fact, usually above the minimum required by salmon and other fish life.

Sufficient has perhaps been stated in the foregoing pages to indicate the great danger of discharging sewage solids into streams, the currents and physical circumstances of which are not such as to ensure the satisfactory disposal of such sewage matter.

Sewage Solids

In every such case the sewage solids should be removed before discharging sewage liquor into the stream.

Streams are to be met with, however, which are capable of satisfactorily disposing of the solids as well as the liquor of crude sewage matter; and it becomes interesting and instructive to consider what may become of the solid matters when discharged into such streams. But little attention has hitherto been paid to this question by engineers and chemists. A good deal of information has, however, been obtained concerning it from recent investigations by water biologists.

In the case of such streams the volume and flow of their waters are sufficiently great to prevent the permanent deposit of the sewage solids discharged into them at any particular point, and to distribute them widely through large volumes of water or over wide areas of clean bed. Under these conditions neither the waters nor the bed of the stream can become fouled, and the former will remain well stored with dissolved oxygen. Other forms of organisms besides bacteria will then flourish, and will feed upon the organic solids thus widely distributed through the waters, or over the bed of the stream.

Microscopic Organisms

Some of these organisms possess the mode of nutrition characteristic of animal forms of life, and do not consequently exercise by their vital processes the drain upon the supply of dissolved oxygen in waters by causing an oxidation of food materials in the way that bacteria do. They consequently do not require so much oxygen for like quantities of organic matter consumed. They can, moreover, it is well to bear in mind, only continue to thrive in well oxygenated water. They are to be found among the forms attached to the bed of the stream—e.g., annulosa, mollusca and large crustacea; among the micro-organisms, which, by reason of the minuteness of their size and feeble powers of locomotion, are carried about passively by the waters of the stream, and include animal organisms,invisible or barely visible to the naked eye, as well as the two great classes of saprophytic and nitrifying bacteria already considered; and, finally, among the various forms of animals—e.g., fish (pisces)—which freely roam through wide areas of water.

The above three categories of organisms occur more or less abundantly in clean river and inshore tidal waters that are exposed to a pollution slight in extent relatively to their volume and flow from agricultural or domestic drainage, and all may assist in the work of the destruction of the solid organic refuse matters in such waters.

The microscopic organisms of fresh and salt waters—termed collectively the "plankton"—have been shown to play a very important part in the consumption of solid refuse matters in waters. These minute organisms are nourished by a true animal mode of nutrition—that is to say, they absorb solid particles of organic foodstuff at any point on their surface—as in the case of the simplest protozoa, digestion taking place within the cell; or, as in the case of organisms higher in the scale of life, they possess a distinct oral aperture, through which the solid particles enter, and an anal aperture, through which undigested portions of food are expelled.

Besides the protozoa, minute crustacea abound in the "plankton" of waters, and of these the most important in sea water are the copepoda. These organisms lead a predatory life, and well deserve the name of scavengers. They feed largely on sewage, and convert sewage into good food for fish. The rotifera also plentifully occur among the "plankton" of fresh water.

Thus, in the "plankton" of a water organisms exist which in their several ways and by their joint action are capable of completely consuming any sewage matters, liquid or solid, that may be associated with them, always provided that the waters shall at all times be well supplied with dissolved oxygen throughout their mass.

That minute organisms possessing a true animal mode of nutrition can consume the solid organic matters of crude sewage at an extraordinarily rapid rate under sufficiently favorable conditions has been proved by the experiments recently carried out in America by Messrs. Edward Barlow and F. W. Mohlan on the "Purification of Sewage by Aeration in the Presence of Activated Sludge" (Journal of Industrial and Engineering Chemistry, p. 318, Vol. 7, 1915). In these experiments crude sewage was nitrified in five hours, and the biological examination of the purified sludge from these experiments showed that among the microscopic animals found were many vorticella and rotifera, but that the predominant organism is a minute worm—Aeolosoma hemprichi. This organism abounds in various kinds of fresh-water streams where there is an abundance of decaying organic material, and thrives especially well where there is much fermentation in waters contaminated with sewage, provided that there is an abundance of oxygen. It belongs to a group of worms in which reproduction occurs very rapidly by asexual methods. It must be noted, however, that, although the purified sludge from the experiments was free from unpleasant odor, and continued to be so, so long as these and other organisms, of which it largely consisted, remained alive or in a fresh condition, it nevertheless became offensive when these organisms died and suffered putrefaction. These experiments afford, therefore, a good illustration of the superiority of water bacteria as scavengers over organisms that are nourished by a true animal mode of nutrition so far as end products are concerned.

Sewage Matters in Streams

But it may be urged that, even when sewage matters are discharged into streams under the most favorable conditions for their satisfactory purification, their destruction as such by living organisms will not be effected immediately, but only after extended periods of time. So that, if any poisonous bodies be associated with the sewage matters, the waters of the stream may remain poisoned for a considerable portion of their subsequent flow.

This aspect of the sewage dilution problem has also been very carefully investigated of recent years, especially by Dr. Houston, for the Sewage Commission and for the Metropolitan Water Board, and his very elaborate and prolonged investigations have clearly shown that the dangers of a properly controlled and limited pollution of a stream by sewage matters are not necessarily as great as has been hitherto supposed. He has shown, on the contrary, that the view hitherto held that a polluted river water, such as the Thames, may be at all times dangerously infected by disease germs is not founded on fact; but that the real danger to guard a river water against, in the interests of public health, is the accidental intrusion of specifically infected excretion from disease carriers.

This conclusion, it may be incidentally pointed out, is entirely supported by the immunity from specific diseases of communities dwelling or working alongside of tidal and non-tidal waters that are polluted often to a considerable extent with sewage matters, and in the habit of making use of such waters for boating and other purposes, including domestic use, except that of drinking.

Antiseptics and certain trade waste liquors would certainly exercise a poisonous influence in a stream if directly discharged into it in the raw condition, or if allowed to drain in too large proportions into a sewer; and where necessary such waste must be specially treated before being discharged into a stream.

But it is the common experience in sewage purification works of towns in which bacterial processes are carried on—e.g., percolating and contact beds filtration processes—that they are not present in sufficient quantity to interfere with the purification of the sewage matter. No doubt they gain access to sewers, but by the time the sewage reaches the purification or outfall works they have either been destroyed or have been so largely diluted as to be rendered harmless to living organisms.

Although the experimental investigations and views referred to in the foregoing pages all go to free slightly polluted river waters from the odium attaching to them as being necessarily sure sources of disease-producing bacteria, the writer wishes emphatically to support the view that, when any river water is drawn upon for a potable water supply to a community, every possible means should be adopted for guarding against the danger of accidental infection, and for ensuring a sufficient chemical purity of the water for all the purposes incidental to the varied requirements of such community.

This discussion of the dilution method of sewage purification may perhaps be fittingly concluded with the following definition of the term "normal" sewage: "Normal" sewage matters are refuse matters, the fermentable organic constituents—both in solution and in suspension—of which can be purified, without previous treatment of any kind, by living organisms.

Fuller Details in Specifications

Continued from page 59

To the credit of engineers be it said that disputes are usually settled on a basis of justice and equity to all parties. Nevertheless much injustice has been done by narrow minded and arrogant individuals who have taken advantage of the literal reading of these clauses. Particularly where the amounts involved are not great. Business men well know that it does not pay to enter into litigation unless the issues at stake are important, because the large corporation or municipality have plenty of money and legal machinery to give battle to the contractor, without any individual suffering personal loss.

These things, however, do not reflect credit upon the ability or character of engineers as a class. Hence we see many contractors voicing a profound contempt for the engineering profession. This is of great disadvantage to the profession at large, and also to the interests of the general public. Engineers, as servants of the public in the highest sense of the term, should maintain a high standard of fairness and justice, as in so doing, they best conserve the interests of their employers. Nothing is to be gained in the long run by endeavoring to get something for nothing from a contractor.

Contractors are as susceptible as a weather vane to the personality of an engineer, and the unfair or unjust individual's reputation will follow him, and will be sure to increase the cost of his work, or, in other words, the cost to the public.

No one will object to the proper safeguarding of the interests of the owner or public, but this can best be done by a fair bargain in which each party knows thoroughly what is required, and each make themselves responsible for their own particular part of the contract, agreeing on a fair method for adjusting unforeseen contingencies which are usually bound to occur.

The Customs receipts of the city of Toronto for the month of December amounted to $2,128,-050—the largest in the history of the city.

Construction Features of Mexico Plant

Described by Mr. R. F. Hayward before Vancouver branch of C.S.C.E.—Fortunately little interfered with by revolutionists

Nearly all of the prominent men connected with the formation and development of the Mexican Light & Power Company's enterprise have passed away in the last few years. Don Porfirio Diaz, President of Mexico, by whose government the enterprise was made possible, died last year. Sir George Drummond, Sir Edward Clouston and James Ross, directors from the inception of the undertaking, and J. D. Schuyler, consulting engineer for the Necaxa Dam, have also passed away. And now but a few months ago Dr. F. S. Pearson, the engineer to whose fertile brain and energy was due the conception, planning and completion of the undertaking, went down with the Lusitania. It therefore seems a fitting time to call to mind some of the features of the Necaxa development, which, for variety of new problems and difficulties met and worked out, is still quite unique in the history of water power development.

Mexico City is situated on a plateau nearly 8,000 feet above sea level, surrounded by a rim of mountains rising from an elevation of from 10,000 to 17,000 feet and including three extinct volcanoes, Popocatepl, Ixtaccihaatl, and The Peak of Orizaba.

A traveller journeying 100 miles in a northeasterly direction from the City of Mexico comes to the rim of a plateau and finds himself suddenly entering a wild mountain region as if from the clouds. These are the slopes from the plateau to the Gulf of Mexico, along which the warm moist air from the gulf, condensed by the cold drift from the plateau above, produces a rainfall which amounts to as much as 150 inches in a year, giving a run-off which, though it varies greatly from month to month, is sufficient to produce large quantities of power from comparatively small watersheds.

The valley of the Necaxa is formed by two limestone ridges and has been filled by successive flows of lava, to a depth of some 1,500 feet. Between the limestone mountains and the lava on each side of this valley the water has cut a channel forming the Necaxa River on the one hand, and its tributary, the Tenango, on the other. At a point some twelve miles below the rim of the plateau this river has cut out a gorge in the basalt 1500 feet deep, and arrives at the bottom in two vertical leaps called Salto Chico and Salto Grande, the upper fall being 360 feet, while the lower one is 740 feet.

The problem presented to Dr. Pearson was to utilize the power of the river going to waste over these falls and to bring machinery for the plant and all that was required for construction into a wild mountain country, where the sole means of communication was a mule trail, and the nearest railway was thirty miles away.

A three-foot gauge railway, thirty miles long, had first to be constructed, and this, owing to the nature of the country, had to be built with curves of the smallest radius possible for Shay locomotives, and with grades as high as 8 per cent.

In order to make use of the mean annual run-off of the watershed of the Necaxa River, four reservoirs were constructed, and later, when it was found necessary to develop more power to meet the rapidly increasing demand, two other reservoirs were built while a series of tunnels, one of which was two miles long, were built to tap adjacent watersheds.

The construction of these reservoirs involved the building of seven earth dams all of them important structures as compared with other earth dams, and two of them, at least, higher than any earth dam that had previously been built. Some of these dams were built entirely by the hydraulic fill method; the others were a combination of core wall, rock fill, clay and earth fill, placed by hand labor, mules and steam shovels, with some hydraulic fill in the centre.

A description of all of these would be beyond the scope of this article, and there is space to refer only to the largest, or the Necaxa Dam. This dam was built entirely by the hydraulic fill method. It was 200 feet high from the bottom of the core trench to the crest of the dam, about 1,200 feet along the crest, and over 1,000 feet on the base from upstream toe to down-stream toe. The slope of the upstream face was three to one, and the down-stream face two to one. The lower toe was a heavy rock fill faced with three feet of rubble masonry laid in cement. The upstream face consisted of the lighter rock fill rip-rapped with stone, and the centre was fine sluiced clay. The total quantities in the dam were about 2,000,000 cubic yards, and in the preparation of the foundations 200,000 cubic yards

First Necaxa Falls, showing temporary plant.

Second Necaxa Falls, 740 ft. high.

Power House and Construction Camp.

of top surface had to be removed. There were three core trenches, one of which was 43 feet deep, and these were built with concrete core walls brought up to a considerable height above the foundation of the dam. All the material was hydraulically filled, and for this purpose a canal twelve miles long was built along the mountain side, bringing a

Necaxa dam from upstream toe showing sluicing trestles.

flow of 35 cubic feet per second under a head of 450 feet, which was used in 6-inch monitors for bringing down the clay and rock.

The material was carried to the dam in wooden V-shaped flumes placed on trestles, which were built up as the work progressed. The material was discharged along the edges of the upstream and the downstream slopes, the rocks and heavier material remaining where they were discharged, and the lighter silts and clays being deposited in the pond in the centre. By this means rocks as big as a man's body were carried through the flumes and deposited in the toes of the dam.

This was the first really large hydraulic fill dam that had ever been built, and as in so many engineering enterprises, when very large undertakings are carried out upon the experience of much smaller works, it was found that the methods previously used had to be materially modified.

While there was a heavy mass of rock fill on the lower toe, the rock fill on the upper toe was comparatively light,

Relief valves of 6-8000 h.p. wheels discharging under head of 1500 ft.

and the fine clay that had settled in the centre not only filled a bigger space than had been originally intended, but it never solidified, and consequently, shortly before the dam had reached its maximum height, the hydraulic pressure due to the head of semi-liquid clay became greater than the light rock toe on the upstream side could stand, and 500,000 cubic yards of material slid out of the dam early one morning. The work was repaired by sluicing a large quantity of rock into the up-stream toe, increasing the rock fill on the lower toe, and then finally filling the greatly reduced space in the centre with sluiced material. The dam, which has been completed for over three years, is absolutely tight and in every way satisfactory.

From a concrete intake tower, built on the upstream toe of the dam, two 6-foot steel pipes about three-quarters of a mile long conveyed the water to the top of the falls. From this point two inclined tunnels each half a mile long, were built on a slope of about 40 degrees, and inside each of these tunnels was laid, on concrete saddles, three 30-inch welded steel pipes. These pipes, which had to stand a head of 1,500 feet, or over 600 lbs., pressure at the lower end, were flanged and welded, and the joints were made by bolting each length of pipe together with loose flanges and a special rubber gasket. The pipes were laid and started practically without a leak, and have been in satisfactory operation ever since. Later, when an extension of the

Necaxa dam, lower rockfilled toe with masonry face.

power house was decided on, a third 8-foot pipe was laid from the dam to the head of the tunnels, and a third inclined tunnel, with two additional pipes, was built.

The power house was located close to the foot of the lower falls. The only access to the site of the power house was by means of a tortuous mule trail down the precipitous sides of the gorge. All the materials for the power house were brought down by means of two 15-ton Lidgerwood inclined cableways, stretched from the top to the bottom of each of the two falls. With these two ways the greatest weight of materials and machinery that could be carried down in a day was about 50 tons, consequently the work of construction of the power house and erection of the machinery was necessarily slow.

The power house consists of a massive concrete steel frame building, in which are installed six 8,000 h. p. waterwheels, driving 5,000 kw. generators, together with an equipment of switchboards and transformers for transmitting the power at 60,000 volts. The wheels are of the impulse type on a vertical axis, so arranged that the high pressure water and the whole of the water wheel is entirely below the generator floor, and are provided with relief valves so that the pressure pipes could discharge in a horizontal direction over the tail race of the power house whenever the pressure exceeded a certain predetermined amount. One of the accompanying photographs shows six of these relief valves discharging at one time under a pressure of 600 lbs.

When it became necessary to enlarge the power house these six water wheels were increased in capacity by enlarging the nozzles, as there was sufficient margin in the

(Continued on page 80)

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

Parliament in any country is alleged to be the boiled down and strained out essence of the people who elect its members. In short, a parliament is a country condensed. But is this true of Canada? This fair Dominion is as much a nation of farmers and manufacturers as the Motherland ever was a "nation of shopkeepers." But if we were to magnify our parliament and produce a country you would have a nation of lawyers and professional politicians with just an occasional farmer or manufacturer stuck in here and there. It would be a nation that would starve to death in the course of a month. Canada's parliament is, therefore, not truly representative of Canada's people—and the blame must rest at the doors of the intelligent electorate.

* * *

But after all, the electorate is not without excuse. When it comes to the polls to cast its vote it is generally offered a choice between a lawyer and a politician. So it does not make a choice. It simply closes its eyes and votes Grit or Tory even as its father voted before it. The successful farmer is busy tilling his farm; the successful manufacturer is busy making a success of his business and the country is left to the politician. The pursuit of money is the root of all evil—and our method of government is one of the resultant evils.

* * *

Politics in this country is a profession by itself. The members of that profession have a political economy all their own. Their ways are not the ways of the Canadian farmer or of the Canadian manufacturer. When one of the latter gets into "the House" he finds himself like the good Samaritan who has—wandered into a strange land. He is allowed to sit in the back benches and watch the wheels go round. In time he either adopts the ways of the politicians or flocks by himself and dies a political death superinduced by loneliness. He must needs vote with his party, condone the faults of that party and sing its praises, else his patronage is cut off and the machine back home either refuses him renomination or damns him with faint support after he is re-nominated. His political life is neither a long nor a merry one. Neither does he become an honorary colonel nor receive recognition at the hands of his sovereign. If you search our long lists of new-born aristocracy can you find a single name placed there because its owner denounced wrong-doing in his own party or stood for the rights of the people against the machinations of the political machine?

* * *

Do you wonder then that truly representative Canadians prefer the paths of private prosperity? Would you ask them to spend the years of their life they are entitled to enjoy trying to fight a system that has become a part, nay practically the whole, of our public life? Do you wonder that we have a Minister of Public Works whose crowning virtue is that he can win elections; a Minister of Trade and Commerce whose one asset is a caustic tongue; a Minister of Militia who can manufacture honorary colonels and grow cub officers that they may live at the expense of the country? It is also much of the reason why each party in turn goes into opposition and waits there till the aroma of certain scandals is carried away by kindly zephyrs.

* * *

American papers are throwing a lot of compliments across the line. The Detroit Free Press, for instance, rises to remark:

"Canada has called for 500,000 troops. Canada is showing England a real example of rising to an emergency."

But Canada has yet a long way to go ere she sticks out her chest and turns her back to be patted by her neighbors. She has given back to Britain the man material from across the seas that has not taken kindly to the tilling of her vacant acres. She has also given of her unemployed and her venturesome. Patriotic they are and brave. They have placed the name of our native land side by side with the bravest nations in the world. They have made the Germans extend the Hymn of Hate to all the far-flung Dominions of the Empire on which the sun never sets. Yet they were sons of a fighting race and they girded up their loins and went forth to battle with a fierce joy in their hearts.

* * *

The real test of sacrifice is now at hand. It comes not in the call for half a million men, but in the answering of that call. It comes when men who love not war but peace, not the blare of trumpets but the quiet fireside, are asked to prove that they love their country more than all else they hold dear in life. It comes when men are asked to give up good positions with the ease and comfort that accompany them, to serve as privates in the ranks—to face hardship and death, not for glory or love of excitement, but as their duty to that Empire that has guaranteed them liberty and the pursuit of a certain amount of happiness.

* * *

Nor has our business community yet learned the real meaning of rising to the occasion. Some lines of trade have been impaired by the war, but on the whole Canada is enjoying a very reasonable prosperity. We have given, some of us, not over liberally to the Red Cross Fund and the Patriotic Fund. We have been pestered by tag days and appeals. But I venture to say that not one of us has been compelled to deprive himself to any serious extent in the giving, while most of us enjoy our usual comforts and luxuries in the same old way. It is no hardship to have to give half a loaf while the baker shop around the corner is still doing business and your bank account shows a goodly balance. It is when you have only one loaf and there is no more in sight that the giving hurts. That time may never come. And if it never does Canada will never have an opportunity to show she can rise to an emergency.

* * *

So far the only actual suffering from a Canadian standpoint has fallen to the lot of the men who have gone to the front, and more particularly their womenfolk who have remained behind. Those who volunteer to fight will continue to be the sufferers, and those who are culling them out should see that none of their sufferings are contributed by their own government. It may be wrong to comment on the "cub" officers who strut about in khaki. Some are doubtless brave boys who will do their bit fearlessly and well. But they are unlearned in the ways of men and liable to be filled with their own importance. Can you, a man of almost middle age, imagine any greater torture than to be lorded over by a boy of eighteen who is earning his first money, not because he is fit to lead men into the valley of death, but because his father had sufficient political pull to secure his appointment? You can't. Well, that is what is happening in scores of places in Canada. Canadians know it and men refrain from enlisting, not because they fear the German shells or gases, but because they might be stood up against the wall and shot for boxing the ears of these same officers. Only the other day I heard a husky private remark: "The first six months after peace is concluded will be the busiest time of the war. We'll have so many officers to lick." It is cheery to report, however, that some of the officers now recruiting units refuse to accept any of the cub variety of officers. They are demanding full-grown men.

* * *

By the way, it looks from here as if Mr. Acton made an awful mess of that Hopkins clothing charge. He made his charge as bold as any lion and then when he got in front of Sir Charles Davidson he wanted to apologize so hard that he hired a lawyer to help him do it. He was evidently so unused to court procedure that he became nervous and engaged a lawyer even more nervous than himself. It never occurred to either of them to ask to have Hopkins' Toronto partner called for examination. To be sure he is a silent partner, but who knows but that the commission might have induced him to break his silence. There was Hopkins' bank account. Might that not have thrown some light on what happened to Hopkins in connection with one or more contracts that seem to have got tangled up with his real estate business. It might have shown where the money came from that is keeping Mr. Hopkins in New York. Or, if Mr. Hopkins' silent partner had been called might he not have been able to explain just why Mr. Hopkins had at this somewhat inconvenient season ceased to bother about clothing contracts and taken such an extended vacation. Mr. Acton either went too far or not far enough. He should never have put his charge in print unless he intended to fight it all the way through. The sudden fright he developed reflects credit neither on himself nor on the trade press.

* * *

For, you know, even if the Purchasing Committee never gave a contract to a real estate man, there is ample evidence that the Shell Committee was not too proud to give a shell-box contract to a shipping clerk or to a general storekeeper. The latter instance occurred down in Victoria County—at Fenelon Falls, to be more exact. The man who got the contract was C. W. Burgoyne, who with his father, forms the firm of W. Burgoyne and Company, which carries on a general store business. Now you can't very well make shell-boxes in a general store, you know, so Mr. Burgoyne looked around for somebody to do the work, and finally sublet to Alfred Tiers, who conducts a small planing mill in Fenelon Falls. The latter couldn't do all the work but by purchasing parts from a third party he was able to complete the contract.

* * *

Before its completion Mr. Burgoyne secured a second contract for an additional 25,000 boxes. This one was handled more scientifically, as Burgoyne and Tiers formed a partnership which did the work under the name of C. W. Burgoyne & Co. Now if the government was anxious to prove that the Purchasing Committee did not let a clothing contract to a real estate dealer shouldn't it be just as anxious to disprove that the Shell Committee let a shell-box contract to a general storekeeper? Isn't it really more necessary that the shell-box matters be cleared up because the Shell Committee was a creature of the Canadian Government handling money in trust for the Imperial Government? The Dominion Government has a sort of right to do as it pleases with its own money, but it owes it to Canada and to the British taxpayer as well, to show that every cent of Imperial funds placed with the Shell Committee was placed properly and to the best advantage. It is up to the Dominion Government to show that the shell-box contract let to a general storekeeper in Victoria County was not placed to relieve either political or "commercial depression brought on by the war."

There has been so much Bertram in this column that some of his friends accuse me of harboring a grudge against the doughty knight. But far be this from the fact. I regret to report that previous to the appointment of the Shell Committee I did not know there was such a person as Sir Alexander on this fertile continent. But you will readily admit there has been much Bertram in the Shell Committee. According to his own modest statement he was simply all of it. He let the contracts and saved the money. Others had been appointed by the Government to assist him in this great work, but he wanted it well done, so he did it himself. Others might be swayed by personal preferences or outside influences. Of himself only was he sure. He burned the midnight oil and wore himself out in health that the Empire might live. We know he did, for he has told us so himself. Consequently, when you discuss the Shell Committee you must discuss Sir Alexander Bertram. All we ever asked for him was fair play—a full and free investigation that would show the grand work he has done for the Empire to which we belong and for Sir Sam Hughes, possibly the greatest of its citizens.

* * *

The Ottawa Journal would now have us believe that the British Government appointed the Shell Committee. Nobody appears to want to own that poor deceased body save and except Sir Alexander Bertram. Wonder if he will wind up by accepting responsibility for its appointment as well as for each and all of its acts.

* * *

One shell manufacturer is credited with the statement that at the end of the year he will ascertain his profit and pay over to the Patriotic Fund every cent in excess of his average usual profits for the last five years. I don't doubt it for a moment. Every man who has received a shell contract is not necessarily a highwayman with a gun held to the Empire's head. Many a shell contractor has taken the work for the joint purpose of giving his workmen employment and furnishing the Empire with the munitions she needs. He neither sought nor received the tremendous profits some others have boasted of making. But with the air full of rumors of tremendous war profits only an investigation will clear the air and let in the light on the vexed question, "Are there profiteers? If so how did they get their contracts?" There must be a reason.

* * *

"We must take steps," said Mr. Walter Runciman, in the Imperial Parliament, "to see that Germany is unable to carry on a trade war against the entente allies after peace is signed." And it is pertinent to ask what Canada is doing in this connection. The allies are so busy whipping Germany into submission that they have little time for after-war plans. But no matter how badly the Teutons are beaten they will emerge from the war with their business organization unimpaired. They will be ready to jump in and command the world's markets the day peace is signed. They must have on hand a tremendous amount of manufactures for which the British fleet has prevented them finding a market. Once the seas are open the Germans will be busy. And the only way to curb their commercial invasion of the allied countries is to build a tariff wall around the central powers. Make it so high and strong that German trade aggressiveness will be held in check till the allies have had time to organize their commercial forces. This defensive measure is necessary from a military as well as a commercial standpoint. For so sure as Germany's commercial campaign is assured, just so soon will she proceed to prepare for another military onslaught on the world.

* * *

A national coal strike is threatened in Great Britain if conscription is put into effect. The Welsh Federation of Coal Miners, by a vote of 163 to 82, adopted a resolution in favor of a walk-out of miners in England, Wales and Scotland, if compulsory military service is inaugurated. If Lloyd George were the strong man his followers would have us believe he would take the leaders of these miners out and shoot them.

* * *

The German peril has disappeared, if indeed there ever was such a thing . . . . . Emergency? Who speaks to-day of emergency? Twelve months have passed since my right hon. friend the Prime Minister introduced his measure (for the construction of Dreadnoughts). Twelve months and more have passed since that time when he saw the German peril. He saw Germany almost ready to jump at the throat of Great Britain. He saw clouds on the horizon; he saw those clouds rent by lightning; he heard the murmurs and rumbling of distant thunder. But my right hon. friend to-day may live in peace. The atmosphere is pure, the sky is clear . . . . . From that time to this moment the relations between the countries, which were cordial in the month of September last, have been absolutely friendly. The light has been let in on that question, and we know now how much the country and the Empire and the civilized world has been deceived upon that question of so-called emergency. We know now, we have the evidence, of how the panics of which we have heard in this House more than once, are created and engineered. We have had the evidence that these panics are engineered by the armor-plate firms, who do not hesitate to create false news in order to obtain contracts for their ships.—Sir Wilfrid Laurier, Jan. 19, 1914.

But let me say this: Everyone knows that for forty years Germany has been preparing for war. For forty years Germany has believed herself invincible and destined to dominate the rest of the world.—Sir Wilfrid Laurier, at Sohmer Park, Montreal, October 15th, 1914.

On January 19 Sir Wilfrid scouted the idea of an emergency. Less than nine months later he declared that "Everyone knows" it. Was he sincere on January 19 or was he just a politician? Does he admit an entire ignorance of the facts or does he plead party exigencies? Whatever the explanation, in the face of such somersaultic statements as the above is it not mere effrontery on the part of Sir Wilfrid to jibe Speaker Sevigny about changes in his political viewpoint? Sir Wilfrid's attitude towards the serious business of to-day is that of a dilettante. He does not take this war seriously. Former friends and admirers who recall the persuasive influence of that "silver tongue," note its continued silence with bitter disappointment.

SEARCHLIGHT.

Personal

Mr. Arthur Reid, Commissioner of Public Utilities for the city of Lethbridge, Alta., has resigned. He is succeeded by Mr. Freeman.

Mr. P. A. McDonald, Winnipeg, has been appointed Public Utilities Commissioner for Manitoba, succeeding H. A. Robson, who resigned some weeks ago.

Mr. R. A. Black, C. E., of Quebec, who has been appointed chief engineer of the district of Campbellton, in place of F. O. Condon, who has removed to Moncton, has left to take up his new duties.

Mr. Norman Murray, formerly chief engineer of Weyburn, Sask., with Mrs. Murray, has left for England. Mr. Murray expects to get a commission when he reaches the Old Land.

Walter Rowland and Robert Livingston, formerly on the engineering staff of the city of Hamilton, have enlisted in 42nd battery and Army Medical Corps respectively. This makes six members of the Hamilton engineering staff who have enlisted.

Pro Patria

Mr. F. B. McFarren, general manager of the Interprovincial Brick Company of Canada, Limited, has recently received an appointment as Lieutenant in the 83rd Battalion C. E. F. Mr. McFarren is well known to the contractors and builders throughout Ontario, having been with Mussens Limited for over five years. He left Mussens in June, 1912,

Lieut. F. B. McFarren.

to accept a position with Mackenzie, Mann & Company, as purchasing agent for the Montreal Tunnel & Terminal Construction, and in April, 1914, was appointed general manager of the Interprovincial Brick Company; he is also a director of the company. Mr. E. G. Glen will be acting manager during Mr. McFarren's absence.

Obituary

A cable received at Vancouver states that Engineer F. F. Pickard, of the Federal Marine Department, was probably lost on the doomed Persia.

The death occurred recently of Mr. R. H. Bradfield, Morrisburg, Ont. The late Mr. Bradfield was prominent in the grain business in the early days, carrying on a business under the name of Bradfield Brothers.

Mr. Hilliard, former member of the town council in Renfrew, Ont., died at his home recently after a short illness. Mr. Hilliard was a building contractor and later founded a brick and tile industry in that town.

Mr. Arthur Pinder, a well-known surveyor in British Columbia, died suddenly in Victoria while walking along the street. The late Mr. Pinder was a native of England, but has been in Canada for many years. He served in the Royal Northwest Mounted Police and was a veteran of the Boer war.

The death occurred in Owen Sound of Mr. Thomas Merritt after a short illness. Mr. Merritt was born in Fredericton, N. B., and was in his 83rd year. For several years he was in the foundry business in Norwich, Ont., going from there to Brandon, Man., where he was agent for the Massey-Harris Company. Fifteen years ago he moved to Owen Sound.

Mr. Alex. Murray, son of T. Aird Murray, consulting engineer, Toronto, died last week in England, as a result of wounds received on the firing line. Mr. Murray was a student at S. P. S., Toronto, when war broke out. He went to the front with the first contingent, as a private in the Queen's Own Rifles, and served through the battles around Ypres. Some months ago he survived an attack of spinal meningitis, and returned to the trenches, only to be fatally wounded shortly afterwards. He will be buried at Newcastle, England, his birthplace.

The death occurred recently of Mr. William Crockett, St. John, N. B. Mr. Crockett was a building contractor, who learned his business in St. John.

Mr. Richard Grigg, Commissioner of Commerce for Canada and the author of several valuable works on trade and commerce, recently died very suddenly in Ottawa. Mr. Grigg was born in Plymouth, Eng., in 1847, but came to Canada at an early age and spent many years on an Ontario farm. Later he engaged in the manufacturing business in England and during that period was an active advocate of Canada and of the urgent need of better understanding of the possibilities of Canada's future in the Motherland. In 1905 he accepted a commission from the British Government to visit Canada and investigate economic conditions here. His report attracted world-wide attention, probably enjoying a larger circulation than any other blue-book ever published. In 1907 Mr. Grigg was chosen by the British Government as head of the British Intelligence Service in Canada. Four years later the Canadian Government appointed him to the position of Commissioner of Commerce with the rank of deputy-minister. This appointment proved an exceptionally happy one, Mr. Grigg's natural ability and wide experience exactly fitting him for the efficient discharge of such an important work.

British Industries Fair

In view of the great success of the British Industries Fair, held at the Agricultural Hall, London, England, from May 10th to 21st, 1914, the Imperial Board of Trade have decided to hold the second British Industries Fair at the Victoria and Albert Muesum, Kensington, London, on February 21st, 1916. The Fair will be open for 12 days.

The Fair will be conducted on the same lines as that of 1915, and is intended to extend to British Manufacturers the same advantages as have been derived by continental manufacturers from the Trade Fairs held in their respective countries. Buyers from the United Kingdom and from all parts of the world are invited to the Fair, and as it is intended for the trade only (the general public not being admitted), buyers will have an exceptional opportunity of transacting their business in a minimum of time.

Manufacturers only will be allowed to exhibit, and their exhibits will be strictly confined to goods of their own make. The Trades exhibiting will be:—Toys; Glassware; Fancy Goods; Earthenware and China; Printing; Stationery.

Admission to the Fair will be by invitation of His Majesty's Board of Trade only, and will be restricted to bona fide buyers for United Kingdom and Overseas Markets. Buyers from the Dominion of Canada visiting the United Kingdom during the course of the Fair, i.e., February 21st to March 4th, and interested in the above mentioned trades, should not fail to communicate immediately on arrival in the United Kingdom with the director, British Industries Fair, 32 Cheapside, London, E.C. It will also be to their advantage to notify the Trade Commissioner's office, 3 Beaver Hall Square, Montreal, giving particulars of the firms they represent, and their addresses in the United Kingdom. Any further information may be obtained from C. R. Woods, assistant to H. M. Trade Commissioner in Canada and Newfoundland.

Building permits in St. Catharines for December amounted to $50,700.

New and Amended Rates in the Hydro Area

We print below the new reduced electric rates for the Hydro area of the province of Ontario. The power rates are exceptionally attractive, and indicate the advantages that must accrue to contracting and manufacturing interests located within that area.

	Domestic		Commercial			Power		
Municipality.	1st 3 KWH per 100 sq. ft.	Additional per KWH	First 30 hrs. use per month.	Next 70 hrs use per month	All over 100 hrs. use per month	1st 50 hrs. use	2nd 50 hrs. use	Add'l Consump.

Mainly Constructional

East and West—From Coast to Coast

Building permits for Victoria, B. C., for 1915, totalled $292,450, of which $50,000 is allowed for repairs.

The Empire Sand & Gravel Company, Limited, Toronto, have obtained a charter.

W. J. Galbraith & Company, general contractors, Montreal, Que., have registered.

Rumble, Mann & Company, railway contractors, Scotford, Alta., have been succeeded by H. Rumble & Company.

Mayor Costello and Commissioner Garden, of Calgary, are offering a reward for the safe return of the stolen city plans.

A syndicate of local capitalists in Pembroke have received an order for 35,000 shells of the value of $200,000. Machinery for the new plant is being purchased.

Lyon-Monkhouse, Limited, Winnipeg, Man., have been granted an order-in-council to change their name to the Lyon Paint and Glass Company, Limited.

1915 was an exceptionally busy one in Listowel, Ont., in the building line, many new homes of the better class having been constructed. The prospects for the present year are also very bright.

The city engineer's report for the city of Stratford shows a total expenditure of $146,011. Nearly twelve miles of permanent roadway, fifty-five miles of sidewalk, and upwards of thirty-three miles of sewers have been laid during 1915.

The Toronto Board of Harbor Commissioners have passed their estimates for the year. They will spend in 1916 $2,500,000—$650,000 for reclamation work, $100,000 for the proposed lift bridge over the Don River at Cherry Street, and the remainder for different construction works.

Mr. J. R. Robinson was elected president of the Master House Painters and Decorators' Association at the annual meeting held in I. O. F. Temple, College Street, Toronto, on the 6th inst. Mr. C. Mandon was elected second vice-president, and Mr. F. J. Cox secretary-treasurer.

The Chatham (Ont.) Builders' Exchange held their annual election of officers on the 4th inst. The following officers were chosen for the ensuing year: president, T. Rayment; first vice-president, A. Tomlinson; second vice-president, C. R. Guy; treasurer, T. McKie; secretary, W. Malvern; auditors, B. Blonde and J. A. Hildreth.

The Precision Manufacturing Company, Limited, has been organized, with head office at St. Catharines, and a capital of sixty thousand dollars, "to manufacture, buy, sell, and generally deal in all kinds of machinery, tools, instruments, and metal articles." The provisional directors are John Frampton, Arthur W. Varey, and M. J. McCarron.

The Eastern Canadian Copper Corporation, Limited, has been incorporated with a capital stock of $990,000, for the purpose of working gold, silver, copper, coal, iron, lead, and other mines. The chief place of business of the company will be Montreal. The incorporators are E. T. Sill, A. J. Perkins, A. O. Whitworth, L. Horsford, and J. T. Whitworth, all of Montreal.

Although the building permits issued in Niagara Falls, Ont., in 1915 totalled $186,906 less in value than those for the preceding year, the figures for the last half of the year that is just closed show a tremendous increase over those for the corresponding months of the previous year. December permits alone amounted to approximately $120,000. Conditions in this city point to a great increase in building activity during 1916.

The December report of the British Amalgamated Society of Engineers shows that the membership has advanced from 173,629 to 204,162 in eleven months, and that funds have increased $1,185,350 in ten months. It is estimated, taking into account the increase in the price of piece work and the amount of overtime worked, that the earnings of members must have been increased by about $10,000,000 a year.

The following is the comparative table, showing the building records of 1915 as contrasted with those of 1914:—

	1914	1915
Montreal	$17,394,244	$7,486,221
Toronto	20,684,288	6,651,889
Winnipeg	12,160,950	1,826,300
Ottawa	4,397,920	1,605,160
Hamilton	3,703,865	1,523,248
Vancouver	4,484,476	1,504,300
London	1,837,735	1,207,630
Halifax	879,320	1,063,985

During the year the Government has built by direct grant 129 miles of new roads and repaired 471 miles of old roads. It has also aided municipalities to build 119 miles of new roads under by-law and to repair 1,250 miles of old roads, thus employing a total of over 10,500 men. The most important piece of work yet undertaken by any provincial government is the high road which will eventually run from Windsor to Toronto and from there to Ottawa and Montreal, connecting at the latter point with the Montreal-New York highway. From Windsor to Ottawa this road will follow the old highway, which was the main artery of settlement in the early history of the province.

Considering the cities through which this will run, and including the population within a four-mile belt on each side, it will serve one-half of the entire population of the province. The section between Toronto and Hamilton, about thirty-six miles long, may be considered the most important. It is almost completely graded, the smaller bridges and culverts are practically finished, and over seventeen miles of concrete pavement have been laid.

The Bricklayers, Masons and Plasterers' International Union of America opened their fifth biennial and forty-fifth convention yesterday morning at the new Central Technical School, Toronto, after parading to that point from the Carls-Rite Hotel, headed by the band of the 48th Highlanders. There were between three hundred and four hundred delegates at the opening, and it is expected that by the end of the week there will be over five hundred in the city.

On arrival at the school the delegates were welcomed by the Hon. F. G. Macdiarmid, who extended to them the freedom of the Province on behalf of Premier Hearst. Mr. Macdiarmid referred to the advance of legislation favorable to the workingmen in the Province of Ontario. He said that after the war Canada would emerge with her credit unbroken, "and when we emerge the brotherhood of man will have a meaning it has never had before."

Mayor Church, representing the city; James Simpson, representing the Trades and Labor Congress of Canada; John Vick, representing the local Bricklayers' Union; James Richardson, representing the Toronto Trades and Labor Council; John Sutherland, representing the Building Trades League, and Dr. A. C. McKay, Principal of the Technical School, also extended welcomes to the visitors.

Mr. W. J. Bowes, who was elected president of the union in 1904, acknowledged the addresses and thanked the various representatives for the cordiality with which the delegates had been received since their arrival in the city.

Sufficient work has now been done at Saanich observatory to give some general idea of what the completed structure will be like. Next month should see a start on the construction of the dome. The concrete base of the structure is in place, and such steel work as can be done pending the return of Dr. Plaskett is now being hastened by the contractors, the McAlpine Robertson Company.

An increase in the price of the tenders for five million bricks resulted in the Montreal Board of Control rejecting the bids of the two companies tendering. The National Brick Company asked $11 per thousand and the St. Lawrence Brick Company $11.25 per thousand, the prices last year being $8.50 and $9.00 per thousand. The bricks are required for sewer work, and the Mayor declared that if no better prices are made the city will consider the use of cement. Fresh tenders are to be called. The price includes cartage. Owing to the large stocks, the companies in 1915 offered the bricks at very low quotations, but this year the makers are asking prices which will allow a reasonable profit.

The New York Continental Jewell Filtration Company, Montreal, is installing a plant at Macdonald College, St. Anne de Bellevue, P. Q. The company has also obtained a contract at Berthier, P. Q., where work will be commenced in the spring. Both plants have a capacity of 300,000 U. S. gallons per day.

A commission representing the city of Montreal, Montreal West, St. Pierre, Lachine, and the Conseil Superieur d'Hygiene have presented a report in favor of converting the St. Pierre River from an open into a covered sewer at a cost of $610,000; also proposing that a barrier be constructed to prevent the St. Lawrence River backing up the open sewer and the construction of a pump house at a cost of $120,000—or $95,000 if electricity be used. The St. Pierre receives the sewage and household and surface water of several municipalities and is nothing less, the report says, than an open sewer.

At the annual meeting of the Quebec branch of the Canadian Society of Civil Engineers held in Quebec on January 11 the following officers were elected: president, Mr. A. E. Doucet; secretary-treasurer, Mr. Ivan E. Vallee; councillors, Messrs. Altheod Tremblay, Gabriel Henry and T. A. J. Forrester.

The Dominion Railway Board have ordered a grade separation at the junction of King Street and the Toronto, Hamilton & Buffalo Railway, Hamilton, Ont., by means of a bridge over the tracks.

Good roads constructed last year in the province of Quebec with the aid and under the supervision of the provincial government, totalled 436.3 miles. Of the total roads constructed 205.6 were macadam, the balance being stone foundation. Since 1911 the province of Quebec has constructed 1,667.67 miles of good road in all sections. The Montreal-Quebec route is on the eve of being completed, which shows that little remains to be done on the Levis-Jackman road. Asphalt work is to be continued on the King Edward Highway.

Canadian Nitro Products, Limited, have been incorporated with capital stock of $5,000,000, to carry on business in Toronto. They will manufacture and deal in war munitions, explosives and ammunition of all kinds. The provisional directors are Edmund Hale Austin, Thomas Neville Polle, Charles Evans-Lewis, D. Finemark and F. Godson.

The British Munitions Company, Limited, have obtained a charter to do business in the city of Montreal; capital stock $50,000. The provisional directors are W. R. Lorimer Shanks, F. G. Bush, G. R. Drennan, Michael J. O'Brien and H. W. Jackson. The company will manufacture and deal in time fuses and munitions generally.

As a result of the success last year of the first conference on highway construction for county road superintendents and engineers, it has been decided to continue the course during the second week of February. Mr. W. A. McLean, Provincial Engineer of Highways, in a foreword to the programme, says: "In an organization covering the southern portion of the Province of Ontario, uniformity of methods and personal touch between the engineers of the department and the county superintendents are essential for the efficient carrying on of highway improvement. The series of lectures on highway construction is undertaken more especially as a means of giving departmental instruction to county engineers and superintendents who are in charge of roads subsidized by the Provincial Government under the highway improvement act."

The conference opens on Tuesday, February 8, and closes on Friday, the 11th. The introductory address will be given by Hon. F. G. Macdiarmid, Minister of Public Works and Highways, and the speakers at the various sessions will include: Messrs. R. C. Muir, A. H. Parker, G. C. Parker, A. A. Smith, W. Huber, George Hogarth, M. A. Kemp, W. A. McLean, W. H. Losee, H. S. Van Scoyoc (Chief Engineer, Toronto-Hamilton Highway Commission), R. M. Smith, Arthur Sedgwick, T. M. De Blois.

Despite the opposition offered to the proposed diversion of the route of the Lake Shore highway from the Lake Shore Road to Queen Street through Mimico, New Toronto and Etobicoke, the members of the three Councils at the conclusion of a conference with Mr. George H. Gooderham, M.P.P., chairman of the Toronto-Hamilton Highway Commission, decided to support the change in route. Mr. Gooderham, in pointing out the material saving which would be effected by the adoption of the Queen Street route, classed the original Lake Shore route as prohibitive in cost, although it was in all probability the people's thoroughfare. To construct the road along the Lake Shore would cost at least $404,000, with the probability that this figure would be increased about $30,000 more owing to land damages. In comparison with this, to build the highway along Queen Street, and thus avoid the big items of expense encountered on the Lake Shore would only cost about $227,000. Under the new plan the road will leave the Lake Shore at the Etobicoke Township boundary line (Etobicoke Creek) and will thence continue along Queen Street through Mimico, New Toronto and Etobicoke, connecting again with the Lake Shore at the westerly limits of New Toronto.

The members of the Toronto Township Council interviewed Sir Adam Beck, chairman of the Ontario Hydro-Electric Power Commission, recently, and discussed the Hydro-Electric radial by-law to be submitted shortly. It is planned to hold the vote on the by-law early next month. Toronto Township's share of the cost of the line is about $355,000.

Construction Features of Mexico Plant

(Concluded from page 62)

generators to produce additional power. But besides this, two 16,000 h. p. units of approximately similar design were added.

The whole design and construction of this plant is of the greatest interest, even though it is not today the newest hydro-electric plant, and when a government in Mexico is formed that compares in any way with the strong effective government of General Diaz, this plant will be of tremendous benefit to the future development of this section of Mexico. It is a remarkable thing that, in spite of all the disturbances in that unfortunate country, the Necaxa plant has never been interfered with to any serious extent.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Hull, Que.
Fire Chief Tessier has recommended that watermains be laid to Tetreville. City Clerk, H. Boulay.

Lynn Creek Valley, B.C.
The construction of a roadway up the Lynn Creek Valley to the Zinc Mines is being considered. The Municipal Council of North Vancouver will approach the Provincial Government for a grant of $5,000 towards the cost of the work, the balance to be provided by the Council and mining interests. Estimated cost, $10,000.

Markham, Ont.
A by-law has been carried providing for the borrowing of $5,000 for the construction of sidewalks. The Village Council will purchase material. Clerk, M. White.

Merritton, Ont.
The Town Council are considering the construction of sewers on a number of streets and the laying of pavement on a portion of Merritt Street. Engineer, F. Rutherford, 24 Queen Street, St. Catharines.

Vancouver, B.C.
Estimates are being prepared by A. D. Creer, Engineer to the Vancouver Sewage Board, on the probable saving if the Stanley Park Causeway and trunk sewer are constructed together. Tenders may be called about the end of January.

Winnipeg, Man.
Plans are being prepared for the construction of watermains to the proposed Institute for the Deaf and Blind, under an arrangement between the Government and the City.

Railroads, and Bridges Wharves

Fort Erie, Ont.
The Buffalo, Fort Erie Ferry & Railway Company, care of F. V. E. Bardol, Room 400, D. S. Morgan Building, Buffalo, N.Y., will apply to the Ontario Legislature for permission to construct a number of extensions to their system.

Hullett Township, Ont.
James Campbell, Secretary to the Township Council, will receive tenders until 2 p.m., February 3rd, for the construction of a steel bridge over Walkerburn Creek. Abutments and flooring of cement construction.

Nanaimo, B.C.
The City Council are considering the erection of a bridge over the Mill Stream and will submit a by-law. Estimated cost, $14,000. Clerk, A. L. Rattray.

Victoria, B.C.
The Canadian Northern Railway Company, Toronto, have prepared plans for a bridge to be erected over Selkirk Water, and have forwarded them to the Federal Government for approval.

Wardsville, Ont.
The bridge for which the County Council are having plans prepared is to be of steel construction, 85 feet span, with creosoted wood block flooring.

Winnipeg, Man.
The City Council are considering the construction of a bridge over the Winnipeg River at Point du Bois, to replace the present temporary structure. Estimated cost, $99,742. Secretary, M. Peterson.

Public Buildings, Churches and Schools

Auckland, Que.
The School Board contemplate the erection of a school, estimated to cost $5,000. Secretary, J. B. Beauvais, Auckland.

Chambly, Que.
The erection of a school is being considered by the School Board. Estimated cost, $3,000. Secretary, G. C. Wallis.

Charlottetown, P.E.I.
Repairs to the First Methodist Church have been decided upon. Work will include the installation of a steam heating system and seating and interior decoration. Secretary of the Committee, E. H. Beer, 134 Richmond Street.

Ditton, Que.
The School Board are considering the erection of three schools, estimated to cost $4,400. Secretary, Tancrede Halle, Ditton.

Hamilton, Ont.
The Board of Education have been informed that a new Collegiate Institute will have to be built during the year, in consequence of overcrowding. Secretary, R. H. Foster, City Hall.

Hampden, Que.
The erection of a school is contemplated. Approximate cost, $5,000. Secretary to the School Board, John Black, Hampden.

Palmerston, Ont.
In connection with the Post Office now in course of erection, the roofing is being done by day labor. Plastering and painting contracts not yet awarded.

Portage la Prairie, Man.
The Public School Board will receive tenders until January 25th for salvage of the walls of the school which was recently destroyed by fire, preparatory to the erection of a new building. Chairman, Dr. A. P. MacKinnon.

Richelieu Village, Que.
The erection of a school is contemplated by the School Board. Estimated cost, $3,000. Secretary, J. C. Bashaw.

Spaulding, Que.
The School Board are considering the erection of a school, estimated to cost $5,000. Secretary, J. Cote, Spaulding.

Stanstead, Que.
The Roman Catholic Congregation are considering the rebuilding of their Church, which was destroyed in the recent fire. Curate, Rev. B. X. Cruveiller

St. Boniface, Man.
A by-law will be submitted to the ratepayers shortly to provide for the erection of an addition to the Provencher School at an approximate cost of $65,000. Chairman of the School Board, J. A. Marion.

Ste. Beatrice, Que.
The erection of a school is contemplated by the School Board. Estimated cost, $3,000. Secretary, Francois Parent.

St. Hubert, Que.
The School Board contemplate the construction of a school at an approximate cost of $3,500. Secretary, W. R. Kennedy, Springfield Park Post Office.

Toronto, Ont.
The Board of Education are considering the construction of an Industrial Farm School, to consist of buildings of the cottage type, each capable of accommodating fifty inmates. Estimated cost, between $25,000 and $50,000 each. Secretary of the Committee, Dr. Helen McMurchy.

CONTRACTS AWARDED

Brighton, Ont.
The contract for plastering at the new school has been awarded to T. Gander & Son, 251 Gladstone Avenue, Toronto.

Louisburg, C.B.
The contract for heating and plumbing at the new school has been let by the Town Council to Charles Thompson, care of Angus McAskill, Glace Bay, N.S.

Verdun, Que.
The contract for painting required in connection with the Nurses' Residence which has been erected at the Protestant Hospital for the Insane, 209 La Salle Road, has been awarded to the general contractors, A. F. Byers & Company, Limited, 340 University Street, Montreal.

Westport, Ont.
The general contract for the erection of St. Edward's Presbytery has been awarded to C. J. Speagle, Westport. Estimated cost, $10,000. Don Valley pressed brick will be used.

Business Buildings and Industrial Plants

Aylmer, Que.
Henry Kuntz, 424 Queen Street, Ottawa, has purchased the site of the Hotel Victoria, which was destroyed by fire,

and contemplates the erection of a large summer residence or hotel.

Cote St. Michel, Que.
The Dominion Government Department of Public Works intend to erect a powerful wireless station to replace the one at Maisonneuve. Secretary, R. C. Desrochers, Ottawa.

Digby, N.S.
Work is progressing on the erection of an office and warehouse for the Nova Scotia Fish Company. Construction is supervised by W. Turnbull.

Forest, Ont.
The Town Council are having plans prepared for fitting up the Town Buildings for Military purposes. Work will include the installation of heating apparatus and general interior fittings. Reeve, F. Patterson.

Halifax, N.S.
The Imperial Oil Company, 311 Dominion Bank Building, Toronto, are building two oil tanks on Richmond St. Special iron construction, concrete foundation. Manager, S. S. Shatford, Halifax.

Hamilton, Ont.
The Royal Hamilton Yacht Club have decided to erect a club house to replace the building which was burnt down last autumn. Work will start in the spring. Estimated cost, $25,000. Secretary, E. J. Renwick.

Kingston, Ont.
The City Council have had plans prepared for alterations to the Market Buildings on King Street for the accommodation of troops. Work will include the installation of closets, sinks, ranges, bunks, etc. Tenders will be called shortly. Clerk, W. W. Sands.

Loco, B.C.
The Imperial Oil Company, Limited, 404 Abbott Street, Vancouver, contemplate the erection of an office building and club house, at an estimated cost of $18,000. Tenders will be called later.

London, Ont.
The by-law to provide for the establishment of a live stock market has been defeated.

Medicine Hat, Alta.
Fefferman Bros., clothing merchants, have purchased a site for the erection of a business block, and will probably start work in the spring. Architect, W. H. Bourne, Huckvale Block.

New Westminster, B.C.
Local architects are now preparing competitive plans for a market building to be erected for the City Council. Tenders will be called as soon as the design is decided upon. Approximate cost, $35,000. Clerk, W. A. Duncan.

Ottawa, Ont.
The Ottawa Brass Manufacturing Company, 367 Wellington Street, are considering the erection of an addition to their factory. Brick construction.

Owen Sound, Ont.
Work by day labor is about to start on remodelling the Pacific Hotel for the Owen Sound Shoe Manufacturing Company, Limited. Promoter, W. E. Wilson.

Peterboro, Ont.
Work is about to start on the erection of an addition to the premises of the Auburn Woollen Mills, River Road. A quantity of steel and other material is already on the site.

St. Thomas, Ont.
The Wabash Railway Company, St. Louis, Mo., have had plans prepared for an addition to their roundhouse. Work will probably commence at an early date.

Strathroy, Ont.
R. M. Pincombe is about to make repairs to his mill, part of which recently collapsed. Approximate cost, $3,500.

Ottawa, Ont.
The City Council have let the following contracts:—supply of one motor, Shepherd & Cameron, Queen Street; two pumps, Mussens Limited, 318 St. James Street, Montreal; boiler, Ottawa Boiler & Steel Works, 135 Broad Street.

Wheel Tax Would Provide Road Maintenance Funds

For the maintenance of roads in North Carolina, Joseph Hyde Pratt, secretary of the State Highway Commission, has recently advocated the imposition of a "wheel tax," based upon tire widths and the amount of damage to highway surfaces caused by individual vehicles. All funds thus collected would be used exclusively for maintenance work. Under the suggested wheel tax a wagon capable of carrying 4,000 lbs. and with wheels having tires 2 to 2½ inches in width, would pay a much greater tax than the same capacity wagon whose wheels have tires 6 inches wide. If the front wheel of such a wagon should not have the same tread as the rear wheels the tax would be still lower. The heavier the load the wagon will hold, the higher, proportionately, will be the wheel tax, and the wider the tire, the lower the wheel tax. With automobiles the horsepower and weight of machine will determine the wheel tax. An equitable scale of the wheel tax can be devised, Dr. Pratt believes, which will not work a hardship on any one and the revenue derived from it will maintain the roads.

In West Virginia lumber wagons have been doing a great deal of damage to the public roads and the county engineers are now putting in force an act recently passed at the extraordinary session of the last legislature, which is as follows:

Persons, firms, etc., making continuous use of any piece of the country road or driving thereon any wagon and by such use causing more than the usual wear, may be compelled to put thereon a section man or men and keep or assist in keeping said road in such repair as the court may order. Any person disobeying or refusing such orders shall be adjudged guilty of a misdemeanor, and upon conviction thereof fined not to exceed $50, or imprisonment, or both.

This action of the West Virginia Legislature, Dr. Pratt thinks, is a move in the right direction, but he is still of the opinion that the wheel tax method of furnishing a maintenance fund and of controlling the damage that vehicles do to roads, is by far the more practical and effective one.

$2,000 Spent by New Society Saves $3,000 to Profession

More than one hundred engineers put in touch with positions, at no cost to the engineer or employer, thereby saving them about $3,000, all at a total cost of less than $2,000, is the gist of the report of the activities of the service clearing house of the American Association of Engineers, presented by the secretary at the first annual convention held in Chicago, December 10 and 11. The $2,000 represents all the moneys spent since this organization, devoted to the welfare of the engineer, started its existence 7 months ago. The work of the clearing house has practically all been done since September 15.

In one-half of the application filed, reported the secretary, there is a steady decrease in the average pay of the engineer from $150 in 1910 to $110 now, a fact that he felt ought to be given serious consideration. While dishonest and incompetent employment agencies are not nearly as prevalent as commonly believed, still instances were given of exorbitant fees charged for positions held only a few days.

The organization has now about 300 members and received 40 additional applications at the Saturday afternoon meeting, which was attended by 400 engineers, 200 of whom were visitors.

In an address by J. H. Prior, chief engineer of the Illinois Public Utilities Commission, on "The Economic Aspects of Engineering Pay," he demonstrated by diagrams that the pay of the lowest "marginal" man in an organization had a direct effect on that of the highest paid. He also pictured the law of supply and demand, showing that the same result was obtained in case free bargaining was indulged in and full knowledge of conditions was known by both the engineer and his prospective employer.

Prof. F. H. Newell outlined the problems of the engineer from the welfare standpoint. He emphasized the idea that this organization is in no wise antagonizing any other good movement, but will stimulate and help the existing organizations far more than it will draw from their membership. He spoke at length on the duty of the society to the engineer and suggested that younger men be chosen more often as officers.

Hauling Equipment that Proved Economical on Road Work

Fifteen teams and ten men were saved on a road contract recently carried out by Thomas Levene near Griffin, Ill., by the use of a White truck and trailer and Lee portable unloaders. In building the asphalt-penetration road, surfaced with three grades of stone, nine dump wagons, each with a team and driver, and three asphalt penetration tanks, each requiring two teams, a driver and a fireman, were in use before the truck was employed. The truck and trailer, making the 4½ mile round trip in less than an hour, including stops, not only hauled as much stone as the nine teams, but also picked up the empty and full tanks as the work progressed, and made the trip from the siding to the job so quickly that firemen were not needed on the tanks. Four men, shoveling all the time into the unloaders, were able to keep the truck and trailer moving without delay.

Tenders and For Sale Department

Tenders Wanted

Tenders will be received by the Council of the Township of Hullett up to 2 p.m. on **Thursday, the 3rd of February, 1916**, for the erection of a steel bridge over the Walkerburn Creek, five miles north of Londesboro, the said bridge to be 60 ft. long and 16 ft. roadway, with cement floor and to be built on cement abutments. The lowest or any tender not necessarily accepted.

3-4 JAMES CAMPBELL, Clerk.

Tenders for Extension of Cold Storage Division—Civic Abattoir

Tenders addressed to the undersigned will be received by registered post only up to 12 o'clock noon on **Tuesday, February 1st, 1916**, covering the extension of cold storage division at the City Abattoir.

Specification may be seen and tender form obtained, together with all information relative thereto, at the Office of the Department of Property, City Hall, or upon application to Mr. D. W. Wright, Manager of the Civic Abattoir, Tecumseh Street.

The usual conditions pertaining to tendering, as prescribed by the City By-law, must be strictly complied with, and envelopes containing tenders must be plainly marked on outside as to contents. A bond from a Guarantee Company, satisfactory to the City Treasurer, will be accepted in lieu of the personal sureties provided for in the specifications. The lowest or any tender not necessarily accepted.

T. L. CHURCH, (Mayor),
Chairman of Board of Control.
City Hall, Toronto, January 12, 1916. 3

Board of Education

Sealed tenders, addressed to the Secretary-Treasurer of the Board, will be received until

Friday, January 28th, 1916
for

Drawing Tables and Side Arm Chairs for Malvern Avenue High School

Ash Hoists, Electric Wiring, Fire Doors, Steam Fittings, at Sundry Schools

Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto. Each tender must be accompanied with an accepted bank cheque for five per cent. of the amount of tender or its equivalent in cash, applying to said tender only. Sureties for all tenders exceeding four thousand dollars must be furnished by Surety Companies. Tenders must be in the hands of the Secretary-Treasurer at his office in the City Hall, not later than 4 o'clock on the day named, after which no tender will be received. The lowest or any tender will not necessarily be accepted.

W. C. WILKINSON,
Secretary-Treasurer.
MILES VOKES,
Chairman of Committee.

Tenders Wanted

Sealed tenders will be received by the undersigned, addressed to Chester S. Walters, Esquire, Mayor, Chairman Board of Control, up to 5 o'clock p.m., **Monday, the seventh day of February, 1916**, for supplying mechanical rakes and appurtenances and travelling hoist and grab bucket (one-half cu. yd. capacity) and appurtenances for Gage Avenue pumping station.

Tenders to be on forms supplied by the City Corporation and plainly marked on the outside as to contents.

Plans, specifications, and further details can be obtained upon application to the City Engineer's office, Hamilton, Ont., Canada.

The lowest or any tender not necessarily accepted.

S. H. KENT,
City Clerk.
Hamilton, Jan. 14, 1916. 3

After All, is Sir Robert the Leader?

Do we understand from Sir Robert Borden's attitude in the House that he refuses to hold an investigation into the charges that have been made in connection with the letting of Canadian munition contracts?

If he knows that the charges are false, would one not expect he would jump at the chance of clearing the reputation of his friends? What is the inference if he refuses?

If he persists in sidestepping the issue we believe Sir Robert has missed the chance of a lifetime to show himself a really big man. Will he prove to be what men are saying of him to-day, or will he measure up to the standard of his opportunities?

The Attorney General seeks to draw a herring across the trail in placing responsibility on the British Government. That's not the issue. The Canadian people want to know whether the men holding executive positions have conducted themselves as becomes appointees of a party holding a great public trust, in accord with the honor of citizens of our great Empire and in the best interests of the efficient conduct of our war.

The original Shell Committee undoubtedly deserves credit for the despatch with which they placed orders among manufacturers, who were naturally shy of accepting the responsibilities of big and uncertain capital expenditures. But what conceivable excuse is there for refusing these same manufacturers further orders—even to the extent of turning down an offer to furnish at cost?

Before the public press became aware of the existing conditions, rumors of what was transpiring reached this paper, and we felt it was our duty to bring certain matters to the attention of our readers. Under the caption "In the Public Eye" we have touched upon, possibly, no more than ten per cent. of the information that has reached us, much of which at the present time is unprintable. It has been our endeavor to cover only such points as would further the common cause, and interfere as little as possible with our national military operations.

As we expected, even in this we have found the path of the pioneer proverbially unpaved. We have the satisfaction, however, of having started a protest that is now being taken up by the independent press even of the Conservative party, and that is ringing from coast to coast among our citizens of influence and power who love honor and efficiency more than money or party. We have the satisfaction of hundreds of friendly assurances that our course has been right, and believe we are backed by thousands more who have read and silently approve our stand.

And now, let us get along with our share in this big war. We have placed ourselves on record, and for the present will let matters rest there. No matter how badly we are led, Canada is in it to our last man, our last dollar, and to our last shirt.

Town Planning Act

The Montreal Chambre de Commerce has passed a resolution asking the Provincial Government to pass a town-planning act, which would allow Quebec cities to take in such adjacent territory and make such arrangement of the territory within the boarders as would allow its development aesthetically and commercially in the most convenient and harmonious manner. The best sanitary conditions, the nearest complete facilities possible for transportation, well-designed arrangements to further the work of the manufacturer and the business man, and sanitary, pleasant dwellings for the citizens were among the details of the plan which the Chambre thought should be included in the powers given in such a law in order that each city should be able to make the most judicious use possible of the territory at its disposal.

Comparative figures of our three chief railways for the first two weeks of the present year and the first two weeks of 1915 show the following very remarkable increases:—

	1916	1915
Can. Pacific Railway	$3,737,000	$2,637,000

Quebec Association of Architects

In the absence of Mr. J. Perrault, president, who is abroad, Mr. Hugh Vallance took the chair at the annual meeting of the Province of Quebec Association of Architects, held on January 15 at Quebec. The report of Mr. J. Emile Vanier, the secretary, pointed out that the year had been devoid of special interest, on account of the war, and that the lack of new buildings had adversely affected the profession. In Quebec, however, the annual report of the Quebec section stated, the depression had not been felt to any extent. The Association had lost three members by death—Mr. R. P. Lemay, Mr. David Ouelett, and Mr. A. I. Richardson, the last-named being killed at Langemarcke, and the Association passed a special vote of condolence with Mr. Richardson's family. On motion of Mr. J. Lebon, seconded by Mr. J. P. Ouellet, it was decided to write the Department of Public Works, Ottawa, asking that members of the Association be employed on Government buildings in the province of Quebec and that the legal fees be paid. It was also decided that the Association should not apply to the Quebec Legislature for charter amendments. The usual banquet was not held owing to the war, and the members further decided not to celebrate the twenty-fifth year of the Association's existence. The following officers were elected: president, Mr. E. B. Staveley, Quebec; first vice-president, Mr. Hugh Vallance, Montreal; second vice-president, Mr. G. A. Monette, Montreal; treasurer, Mr. N. MacVicar, Montreal; secretary, Mr. J. Emile Vanier, Montreal; council, Messrs. M. Eug. Payettte, Frank Peden, Alph. Piche, H. J. Asselin, J. Lebon; delegates to the Royal Architectural Institute of Canada, Messrs. Joseph Perrault, Alcide Chausse, D. R. Brown, Jos. P. Ouellet, A. Beaugreand-Champagne.

Department of Public Highways

It is now formally announced by the Ontario Government that a separate Department of Public Highways has been created. The new department will be in charge of a Deputy Minister, to which position Mr. W. A. McLean, Provincial Engineer of Highways, steps up. Hon. Finlay Macdiarmid will in future be known as the Minister of Public Works and Highways. This latest move on the part of the Ontario Government indicates their intention of prosecuting vigorously the development of highways at various points in the province. Provision is made for the construction of suburban and township roads in addition to county roads. An efficient system of maintenance of roadways will also be inaugurated.

The province is to be congratulated in that an appointee with the personality, ability, and experience of Mr. W. A. McLean was available for this position. Under his guidance we have no doubt that the highways of the province of Ontario will be rapidly improved and maintained in the most efficient and economical manner.

Honored the New Knight

Sir John Kennedy, the consulting engineer of the Montreal Harbor Commission, was, on Saturday, January 15, entertained at dinner by the staff of the Harbor Board to celebrate the honor of knighthood conferred on their colleague. Major David Seath, the secretary, presided, and referred to the long service of Sir John, and to the important works with which he has been identified, including the development of the port of Montreal. Notwithstanding Sir John's blindness in later years, he has designed many works, one being the fine piers at Halifax for the Department of Railways and Canals. Replying to the toast of his health, proposed by Mr. F. Robertson, Sir John acknowledged the congratulations which he had received, and said that the work done during his thirty-three years with the Harbor Commission was not as prominent in his mind as the men who had worked with him in securing that development. The health of the engineering department was replied to by Mr. F. W. Cowie, chief engineer.

Annual Meeting C.S.C.E.

The annual meeting of the Toronto Branch of the Canadian Society of Civil Engineers, at which the report of the retiring secretary was presented, shows that the Branch is in a healthy condition, both as to finances and membership. The figures indicate that the Toronto membership is now 344, or an increase of 49 over the year 1914. During the year valuable contributions to the literature of the Society were made in some half dozen addresses by prominent Canadian engineers, including Mr. W. McNab, Mr. T. T. Black, Dr. J. A. Amyot, Mr. H. S. Van Scoyoc, and Mr. J. A. D. McCurdy. The annual excursion of the Branch consisted of an inspection tour of the construction work of the new Welland Ship Canal. Various reports were presented by the different committees which had been appointed earlier in the year for this purpose, and these reports were forwarded to Montreal for incorporation in the general report to be presented at the annual meeting of the Canadian Society of Civil Engineers in Montreal on January 25, 26 and 27.

The following officers were elected for the coming year: president, Mr. G. A. McCarthy, engineer of Railways and Bridges of the city of Toronto; secretary-treasurer, Prof. Arkley, Department of Applied Science and Engineering of the University of Toronto. Executive committee: Messrs. E. W. Oliver, assistant engineer, C. N. R.; A. H. Harkness, consulting engineer; A. L. Mudge, consulting engineer; and H. G. Acres, hydraulic engineer, Hydro-Electric Power Commission of Ontario. During the past year the Toronto branch of this society has shown very effective evidence of a determination to make the operations of this branch an essential part of the proceedings of the parent society.

At a meeting of the Quebec Superior Board of Health, held in Montreal on January 14, it was decided to ask the Government to increase the grant of $35,000 to supervise the execution of the Health Act in the province. The members suggested an increase from 1¾ cents per head of the population to 2½ cents, which is lower than is paid in other provinces. The board approved a committee's report on the restrictions that should be made to the use of chlorine for the correction of water supplies. Chlorination cannot fill the place of filtration; as it is quickly set up, it is of great help in an emergency until a permanent filter plant can be provided. On the report by the sanitary engineer that the water supplies of the cities of Hull and Aylmer were polluted, the board ordered the secretary to serve a notice on the authorities of both cities to appear before the board, municipalities having to be heard before remedial measures can be considered by the board.

The City of Montreal Filtration Works

The necessity of a better quality of domestic supply recognized by the increasing death rate—Features of the new works described—Constructional difficulties—Cost figures

By Frederick E. Field*

The water used by the citizens of Montreal is obtained from the St. Lawrence River and is distributed to the consumers by two entirely independent corporations. The Montreal Water and Power Company, a private corporation, has a shore intake and has purified its water supply since June, 1912, by means of a mechanical filtration plant. This company supplies approximately 27 million gallons daily to about 250,000 people, including many residents of adjoining municipalities. The municipal plant of the city of Montreal has both a shore and a mid-stream intake, situated about two miles above the Lachine Rapids of the St. Lawrence River. From an entrance gate chamber which receives the supply from both intakes, a concrete conduit 8½ feet in diameter, conveys the water to the Low Level Pumping Station, from which it is pumped through the distributing mains to the city's reservoirs. This station supplies between 50 and 55 million gallons daily to approximately 400,000 people.

Need of Purification

For many years the excessive number of cases and deaths from typhoid fever has shown the necessity of improving the quality of the water used for domestic purposes.

The increasing pollution of the water supply, due to the discharge of sewage and other impurities from towns within the drainage area above the intake is indicated by Fig. No. 1, which shows graphically the total number of deaths and the death rate, per 100,000 population, from typhoid fever for a long period of years. During the late fall and winter of 1909-1910, a severe epidemic of typhoid fever prevailed in Montreal and its suburbs, and occasioned 203 deaths between October 1st, 1909, and March 1st, 1910. The necessity for prompt action was recognized by the city officials, and on February 8th, 1910, the treatment of the municipal water supply by hypochlorite of lime was started, and has been regularly continued to the present time. On April 4th, 1910, Messrs. Hering and Fuller, filtration engineers, were instructed to report on the best means of securing an improved water supply for the city. On July 2nd, 1910, these engineers submitted their report and recommended filtration of the St. Lawrence River water. Their recommendation was adopted by the city and Messrs. Hering and Fuller were engaged to co-operate with the late Major Georges Janin, then chief engineer, in preparing plans and specifications and in supervising the construction of filtration works for the city of Montreal.

General Description

The filtration works, which are now practically completed, with the exception of the placing of the filtering material, are designed for a nominal daily capacity of fifty million Imperial gallons.

A nine-foot concrete conduit connected to the 8½-foot main supply conduit, previously mentioned as supplying the low level pumping station, will bring the untreated St. Lawrence River water to what is known as the Filtration Pumping Station. A five-foot branch from this nine-foot conduit, permits of a second source of supply to the filtration works, namely from the Aqueduct. This five-foot, or emergency, intake will only be used when the main supply conduit is not in service or when its capacity is not alone sufficient for the daily use of water by the city, as the aqueduct water is more highly polluted than water obtained from the mid-stream intake of the St. Lawrence River. The purpose of the filtration pumping station is to lift the conduit or aqueduct water to the prefilters, a height of approximately 18 feet, and to furnish water at a higher pressure for washing the prefilters at times of cleaning. From the prefilters, or rapid-filters, which is the first step in the purification process, the water will flow by gravity to the final filters, which are quite similar in construction to the usual slow sand filters.

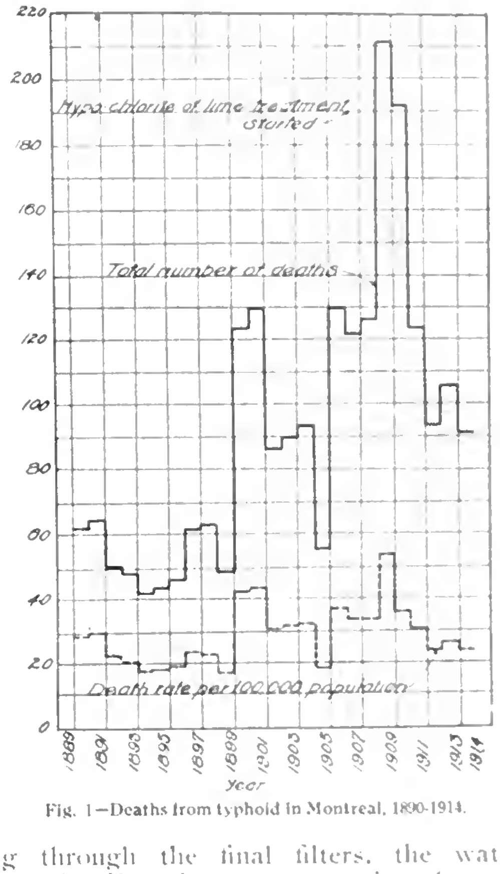

Fig. 1—Deaths from typhoid in Montreal, 1890-1914.

Passing through the final filters, the water will flow into the filtered water reservoir, where, if it is deemed desirable, it will receive a final purification by treatment with hypochlorite of lime. No chemical treatment of the water will be made prior to its reaching the filtered water reservoir and such treatment at this point may not be found necessary during certain periods of the year.

From the filtered water reservoir the purified water will again flow to the filtration pumping station, from which it will be pumped to the present low level pumping station, where it will be forced by high pressure pumps through the distributing mains and to the

*Resident Engineer.

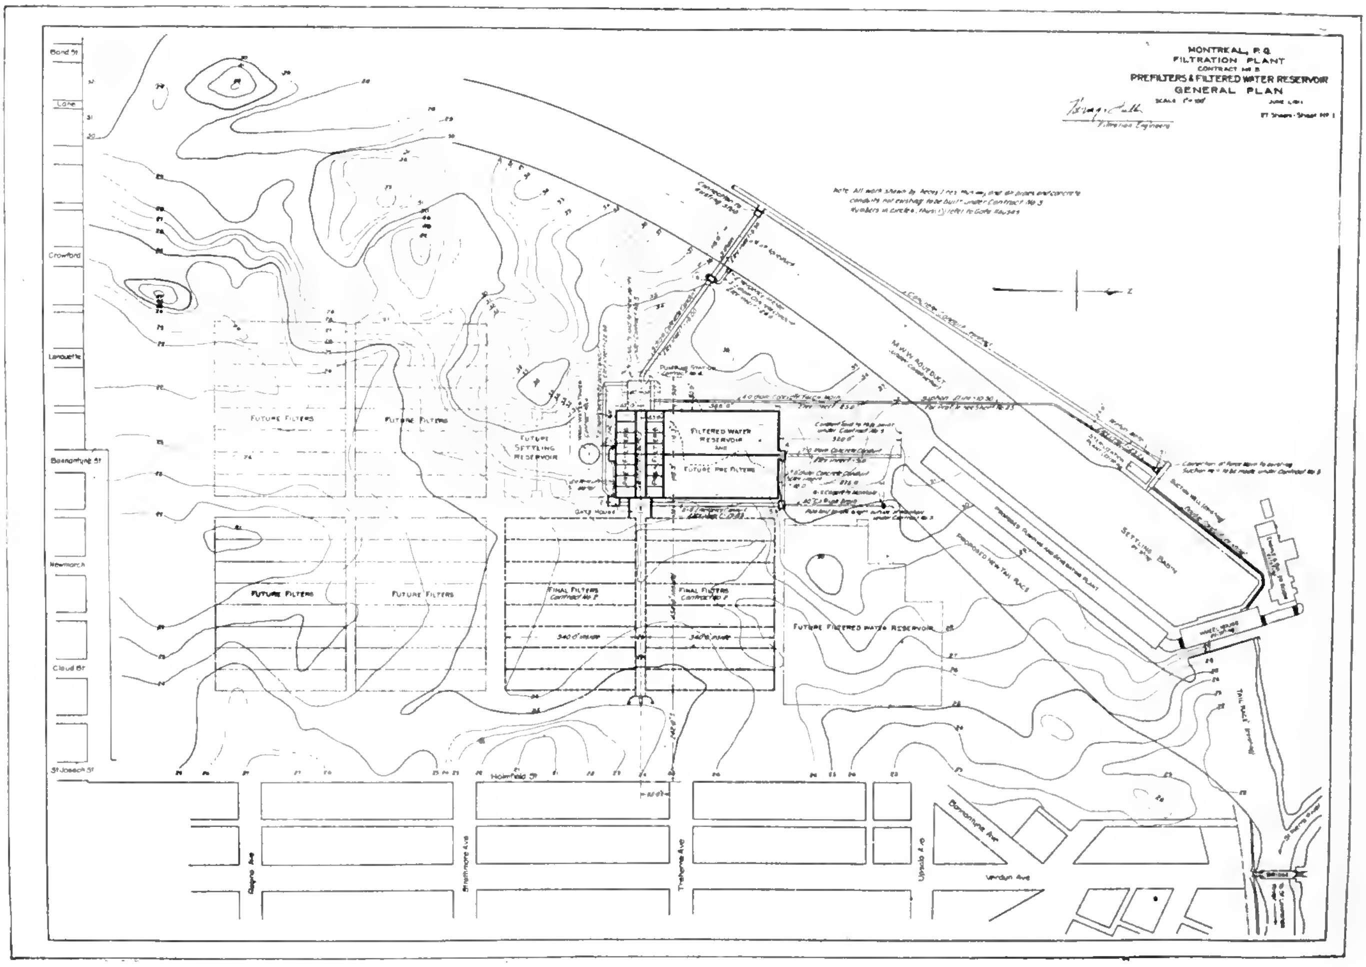

Fig. 2—General Arrangement of Filtration Works, Montreal.

reservoirs. After the completion of the aqueduct enlargement work, which is now under construction, the filtered water will not return to the filtration pumping station but instead will flow by gravity from the filtered water reservoir to the new hydro-electric pumping station at the end of the aqueduct, and from this point will be delivered through the distributing mains to the consumers. Fig. 2 shows the general arrangement of the filtration works and its relation to the aqueduct and pumping station.

Filtration Pumping Station

The filtration pumping station, Fig. 3, is a two-storey structure about 80 ft. x 60 ft. in size. The lower storey is below the ground level, and is traversed by the raw-water suction conduit and the raw-water discharge conduit, which are placed one upon the other. The direct connected motor driven, centrifugal pumps are arranged on either side of the central conduits in such manner as to obtain their supply from the lower, or suction conduit and deliver into the upper or discharge conduit with a minimum of piping connections. Four of the pumps on the north side of the station are also similarly connected to a filtered water suction conduit and a filtered-water discharge conduit, and provided with suitable check and controlling valves. This will permit of one or all of these pumps on the north side of the station to be used for delivering filtered water to the present low level steam pumping station until such time as the new hydro-electric pumping station is completed, after which, as previously stated, the filtered water will flow by gravity to the new pumping station, and all raw-water pumps in the filtration pumping station will be available for supplying the filters.

The pumping station includes the following units:

4 raw water pumps,	unit capacity	17,500 Imp. gal. per min.
2 raw water pumps,	unit capacity	11,600 Imp. gal. per min.
2 raw water pumps,	unit capacity	5,800 Imp. gal. per min.
2 wash water pumps,	unit capacity	1,300 Imp. gal. per min.
1 sump water pump,	unit capacity	330 Imp. gal. per min.
1 sump water pump,	unit capacity	150 Imp. gal. per min.
1 rotary blower,	unit capacity	5,000 cu. ft. air per min.

Switchboards, transformers, cranes and other equip-

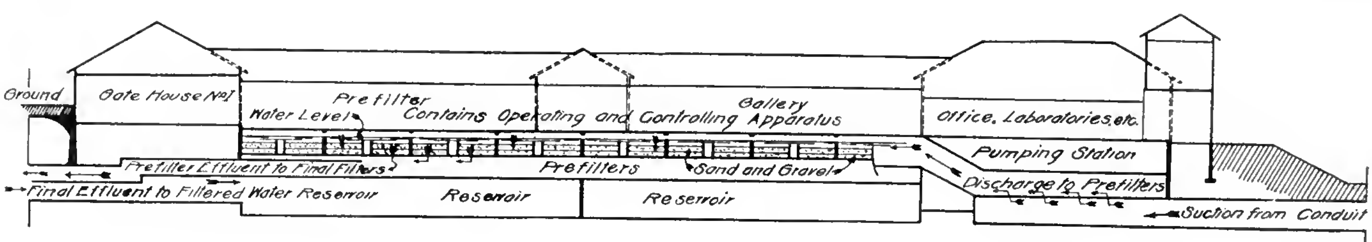

Fig. 3—Section of the Filtration Pumping Station and Prefilters—showing course taken by water.

ment are provided to make the installation complete. The wash water pumps and the blower are for use in seepage and drainage water. The six largest pumps and the blower are operated by motors using 2200 cleaning the pre-filters. The sump pumps will remove volt alternating current. The other pumps operate under 550 volt current. The upper storey of the pumping station is above the ground level and, similar to all other buildings of the works, has walls of red brick and cinder concrete roofs covered with green tiles. The north side of this upper storey contains a laboratory for water analysis and other purposes usual in the operation of filtration works. The south side contains rooms for storage and other needs. Fig. 4 shows a section of the pumping station.

Pre-filters

The pre-filters, located east of and adjoining the pumping station, are supported by groined arches above the roof of the filtered-water reservoir. They are sixteen in number, each having a net filtering area of 1,200 square feet, and are arranged eight on each side of a central operating gallery. Each prefilter is divided longitudinally by a central gutter into which empty the sixteen laterial reinforced concrete wash-water gutters. The strainer and air system is made up of cast iron headers and 2-inch cast iron laterals, with brass strainers spaced on 6-inch centers. The filtering material consists of 15 inches of gravel, graded into four sizes and placed in corresponding layers, and 30 inches of filter sand. The details of a prefilter unit is shown in Fig. No. 5.

Longitudinally through the centre of the operating gallery are two concrete conduits, placed one upon the other. The upper one is the raw-water supply conduit from the filtration pumping station and the lower is the prefilter effluent conduit leading to the final filters. These two conduits are connected to the prefilters by cast-iron piping with hydraulic controlling valves. All these valves and also the valves for wash water, air, and drainage are controlled from sixteen operating tables on the gallery floor, one operating table being located in front of its corresponding filter. For controlling the rate of filtration, rate controllers of the Earl type are provided. These are so connected to a master controller that the discharge from the prefilters is automatically adjusted to the discharge from the final filters, which in turn is similarly automatically controlled by the amount of water being drawn from the filtered water reservoir. In other words, the plant as a whole will deliver filtered water at the same rate as it is being used in the city without man operation of the many controlling valves. All other features of the prefilters are of the usual construction and need no detailed description. Fig. No. 6 shows the completed prefilter gallery.

Final Filters

The final filters are sixteen in number, and, similarly to the prefilters, are arranged eight on each side of the operating gallery. The filters are covered by groined arches supported by piers spaced on 19 feet centers. The pier load is carried on foundation blocks independent of the rest of the floor, which is flat, and but five inches thick. The filters are each 55 x 340 feet, inside measurements, with the short dimension

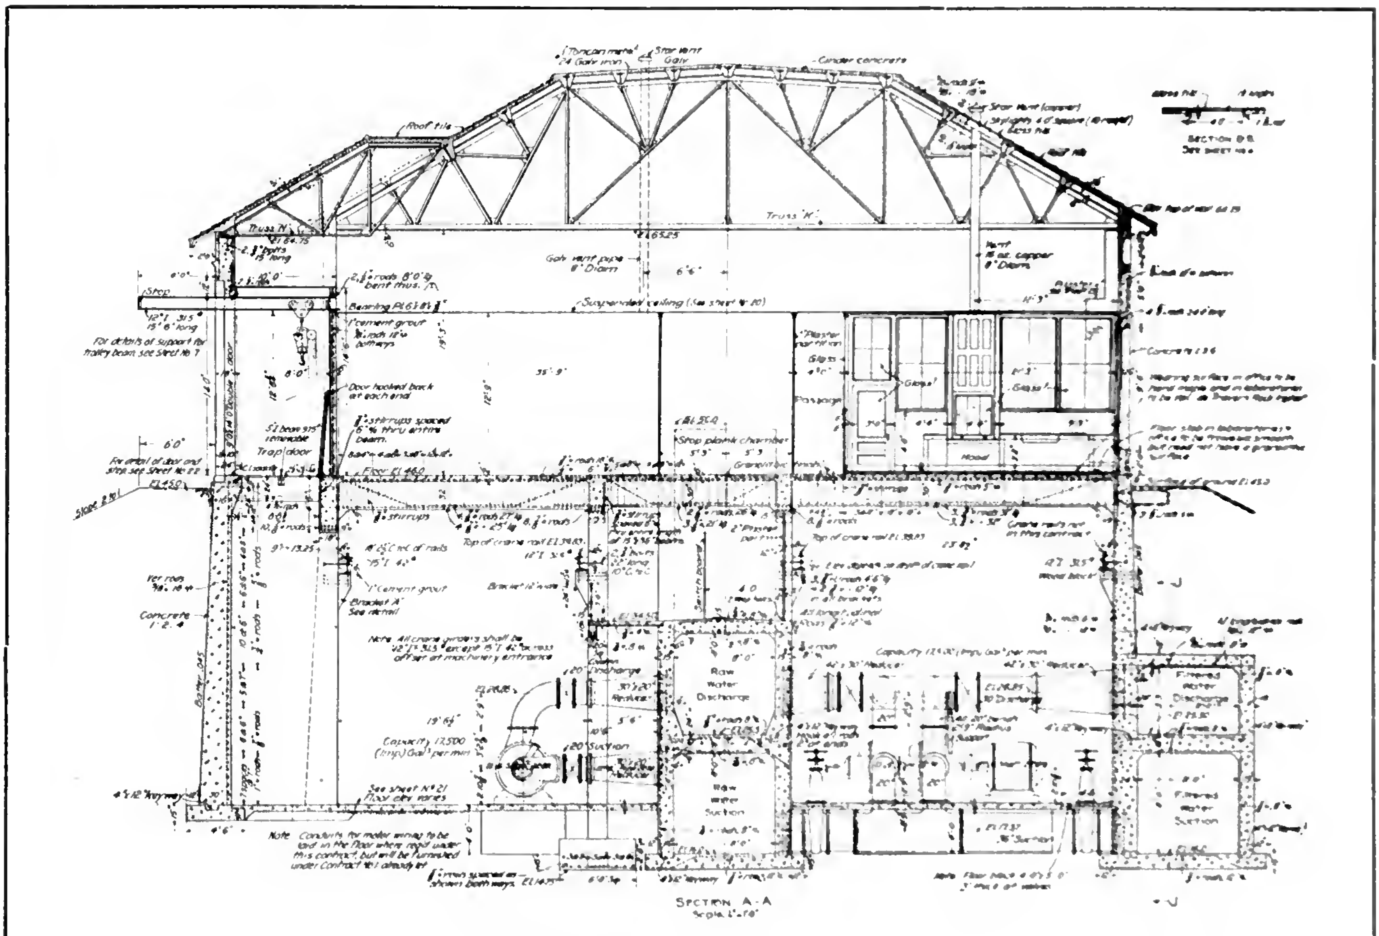

Fig. 4 Section of Filtration Pumping Station.

adjoining the gallery to better accommodate the use of Blaisdell washing machines for the filter cleaning. The underdrainage system consists of two half round 8-inch tile laterals in each bay, which discharge into a central main collector, 2½ feet in diameter, extending the entire length of the filter below the floor level.

A heating and ventilating system is provided to prevent skin ice forming during the winter months and interfering with the free movements of the washing machines, and also to make the filters more healthful and comfortable for the workmen. This consists of a fan and a system of air ducts so arranged that

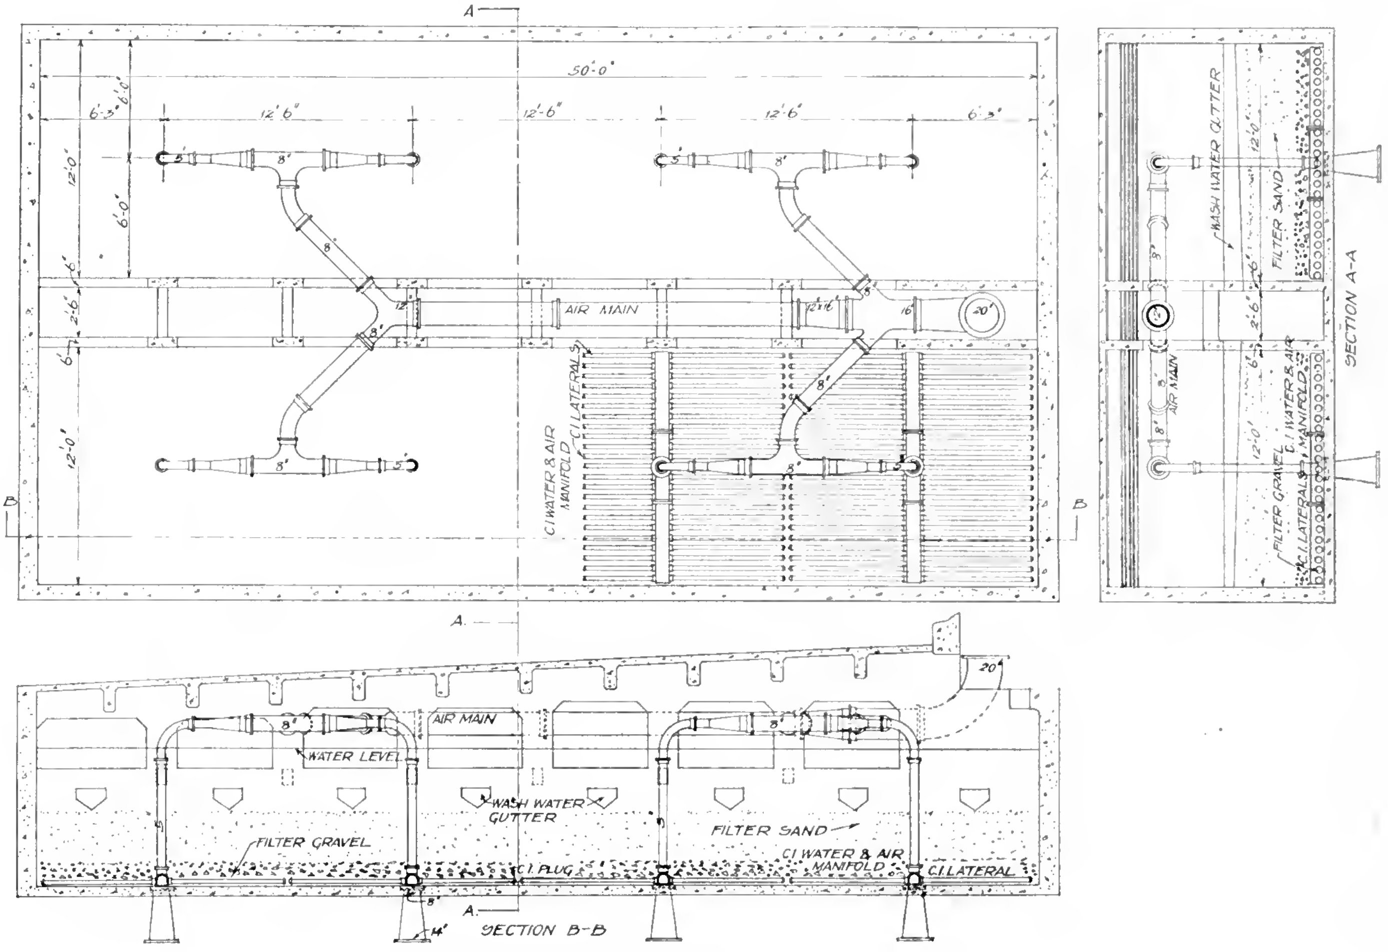

Fig. 5—Details of the Prefilters—Montreal Filtration Plant.

The filter material includes 12 inches of graded gravel, placed in four layers, and 27 inches of sand. The conduits and piping connections in the gallery, including the Earl rate controllers, are similar to those of the prefilters. The periodical cleaning of the final filters will be accomplished by Blaisdell washing machines. These machines, travelling on tracks supported by the piers, will rake and wash the upper layers of the sand, leave the sand bed clean and uniform, and pump away to the drains all dirt and other foreign matters which have accumulated since the previous washing. All this will be accomplished at one operation and by one man operating the machine.

Among the advantages of this method of cleaning the filters are:—

(1) The length of time the filter is out of service is a minimum.

(2) The removal of the dirt from the sand is more complete than can be done by hand cleaning as the cleaning process extends to any desired depth below the surface of the sand.

(3) The sand bed is left more uniform and without the compacting which accompanies the walking over the sand by workmen.

(4) There is no break in the regular routine of the work during the winter months and no decrease in the effective filtering areas.

heated air can be blown uniformly over the entire area of the filters. Fig. No. 7 shows the details of design of the final filters, and Fig. No. 8 is an interior view of the completed final filter gallery.

Filtered Water Reservoir

The filtered water reservoir is of concrete with groined arches for the roof and inverted groined arches for the floor. It is about 430 x 232 feet in size and has a capacity of 6¼ million Imperial gallons. With the exception of its use to control the output of the plant, as has previously been described, there is nothing unusual in its design or method of operation.

Electrical System

The Montreal filtration works uses electric current for power, heating and lighting. Until the completion of its own hydro-electric power and pumping station, the city will obtain electric current from the Montreal Light, Heat and Power Company, which has a 10,000 volt transmission line near the works. Branch connections from this transmission line will bring 10,000 volt alternating current to the filtration transformer building, where it will be reduced to 2,200 volts and transmitted through an underground conduit system to the filtration buildings. Here it will be used at the same voltage for the motors operating the main pumps or reduced to 550 and 220 volts for other mach-

Fig. 6—Completed Prefilter Gallery.

inery and for lighting and heating. Heating throughout the entire works will be accomplished by electric radiators. The Blaisdell washing machines use direct current, consequently a motor generator set is provided to supply this current to the machine motors through the three miles of double trolley lines by which the machines are operated in the final filters.

Exterior Appearance of Completed Work

In the centre of a level tract of land nearly 100 acres in extent, mounds of earth with neatly trimmed slopes, and several red brick buildings with green tile roofs give but little indication of the extent of the many and interesting features of the filtration works there located. Of the ten acres covered by the present works, over nine acres, including the final filters, prefilters and filtered water reservoir are entirely underground. The pumping station, prefilter gallery building, wash water tower and the several gate houses, serve to identify the several divisions of the works. It only requires the extension of driveways and the planting of trees and shrubs to convert the filtration lot into a spacious park which will not only be appreciated by the nearby residents, but will also give the city of Montreal an attractive setting to one of its most beneficial public works. The approximate cost of the work is given in the following tabulation:

Delays in Construction

Contracts Nos. 1, 2 and 3 were awarded in the late summer and fall of 1911, and when the work under these contracts was sufficiently advanced, the other contracts were awarded in logical order. Very little work was accomplished in the final filters, prefilters and filtered water during 1911, and it was not until July, 1912, that the first contract was placed. The progress during 1912 was also slow and unsatisfactory, due to unwise selection of plant and organization by the contractor on contracts Nos. 2 and 3. During the winter of 1912-1913, failure on the part of the contractor to protect the floors and foundations of the final filters against damage by frost action, resulted in a general upheaval of the foundation of the walls and piers, the cracking and lifting of the filter floors, the collapse of many of the main collectors and miscellaneous other damage. Much of the spring and early summer of 1913 was occupied in an investigation of this damage and resulted in the contractor acknowledging his responsibility therefor. The troubles on contracts 2 and 3 seriously delayed the work on the other contracts, and September 1st, 1913, the date specified for final completion of all the contracts, found the filtration works in a sad state of incompleteness. During 1914 and 1915 the work progressed at a slow and unsteady rate on contracts 2 and 3, due largely to organization and financial

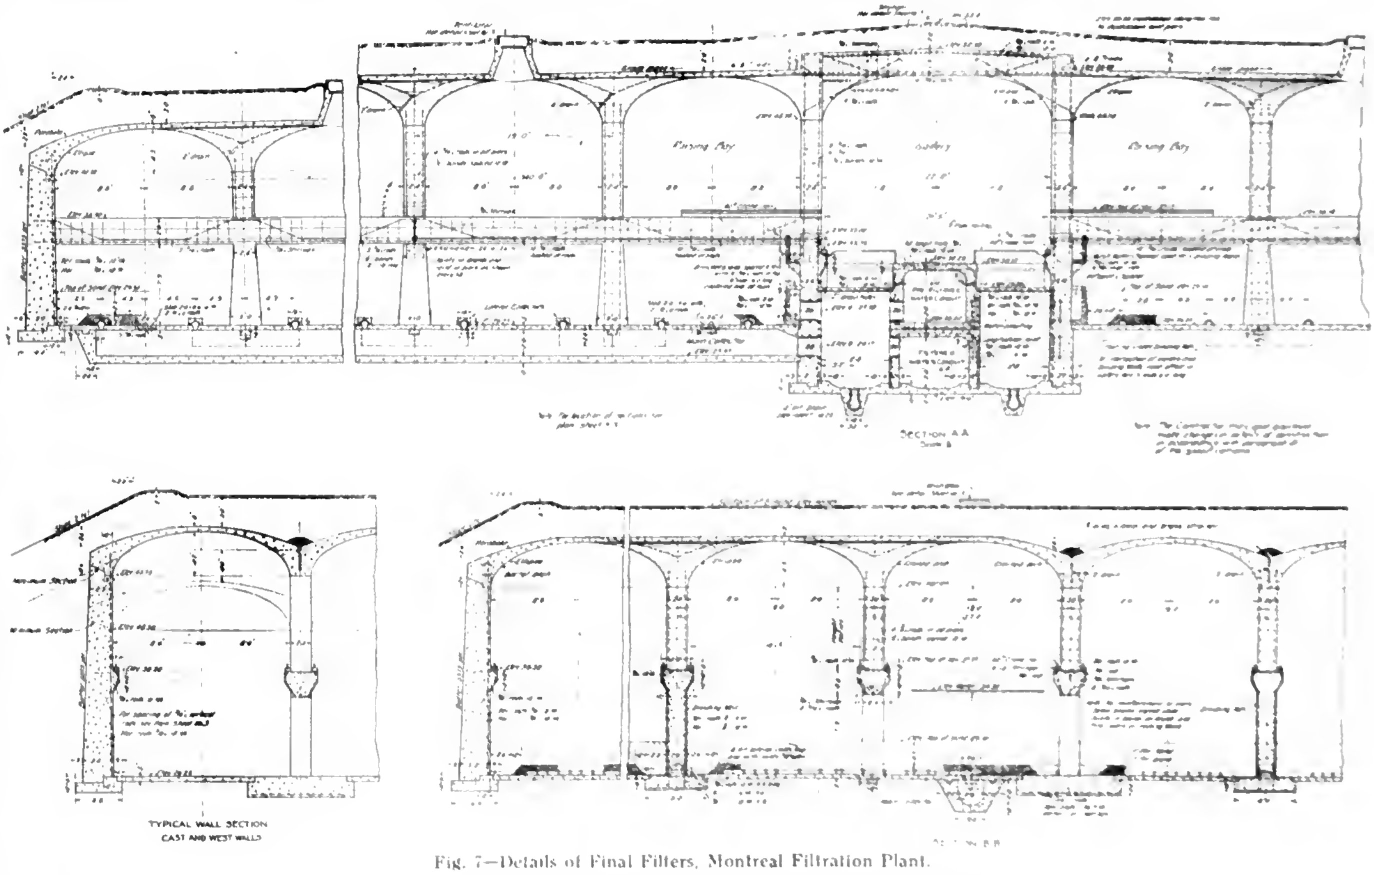

Fig. 7—Details of Final Filters, Montreal Filtration Plant.

Table I.—Filtration Contracts

No.	Description	Contractor	Value
1.	Pumping machinery, blower and cranes	British Electric Plant Company	40,250
2.	Final filters and appurtenances	F. H. McGuigan, transferred to Norman M. McLeod	673,000
3.	Pre-filters and filtered water reservoir	F. H. McGuigan, transferred to Norman M. McLeod	485,000
4.	Pumping Station, wash water tower and buildings	F. J. Jago Company, Limited	159,500
4a.	Interior painting	Charles Larin	1,250
5.	Exterior electrical conduit system	G. M. Gest	6,000
5a.	Underground electrical cables and appurtenances	Northern Electric Company, Limited	12,500
6.	Transformer building	City of Montreal	6,000
		Approximate total value	$1,383,500

troubles. The progress on all other contracts has been quite satisfactory considering the many impediments to rapid completion. On January 1st, 1916, all work is so far completed that the operation of the plant is only prevented by the lack of filter sand and gravel. It is expected that this very important item of the work will be rushed to rapid completion during the coming season and that before the end of the year 1916, the citizens of Montreal will at last realize their long felt need, namely, a pure and wholesome water supply.

Need of Extensions to Filtration Works

In 1910, when the design of the filtration works was started, the amount of water supplied by the municipal waterworks was about 37 million Imperial gallons per day. The filtration works were designed for a nominal daily capacity of 50 million gallons, which was one and one-third times the daily water use in 1910. It was realized at the time that extensions to the filters would be required in a few years, and provisions in the designs of the works now constructed allow for extensions with but little difficulty and without serious disturbance in the regular operation of the plant. Annexations of adjoining municipalities and the large extensions of the city's water distribution system have, however, been much more rapid than was expected. From 1910 to 1915 the water used has increased from 37 to 55 million gallons per day, and the filtration works now nearing completion will be required to work at full capacity from the day it is put into service.

Fig. 8 - Final Filter Gallery.

The need for immediate action to provide for a daily capacity of 100 million gallons of filtered water is so apparent that the city will undoubtedly, in the near future, let contracts for the extension of the present filtration works.

The filtration works and other waterworks improvements are being carried out under the general supervision of Messrs. Paul E. Mercier, Chief Engineer of Public Works, and T. W. Lesage, Engineer Superintendent of Water Works.

Toronto Builders' Exchange

At the annual meeting of the Toronto Builders' Exchange, held on January 17th, the following officers were elected:—President, S. R. Hughes; first vice-president, W. E. Dillon; second vice-president, Walter Davidson; treasurer, John Aldridge. Elected Directors: Fred Armstrong, Ed. Gearing, Geo. Gander, Chas. Bulley, A. D. Grant and five directors still to be appointed. Mr. Geo. Oakley, the retiring president, stated in his report that the new form of contract upon which the Exchange had been working for the past two years, had been adopted and was now being used by practically every architect throughout the Dominion. Reference was also made to the work of the Exchange in connection with the Workmen's Compensation Act. A motion was adopted requesting members to forward a carbon copy of all reports of accidents, to the Secretary of the Exchange. The financial report showed a good balance. Mr. Arthur E. Flower, Secretary for the past three years, was tendered the hearty thanks of the retiring officers for his efficient work during 1915.

A paper entitled "Studies for and Experiments with Mixtures for Winnipeg Concrete Aqueduct," by W. G. Chace and D. L. McLean was read on January 6th, 1916, before the Manitoba Branch of the Canadian Society of Civil Engineers. This paper dealt with the methods used to ensure water-tight concrete for the Great Winnipeg Water District Aqueduct. It will be presented to the Main Society for publication at a later date.

Construction of City Pavements

Methods employed by different Engineers in laying Stone, Brick, Wood and Bituminous Pavements—The importance of Maintenance and Repairs

By Geo. W. Tillson*

So much has been said in recent years regarding the detailed construction of different pavements that it does not seem necessary to repeat it here. It perhaps would be of more interest and value to discuss somewhat in detail the different points of these pavements concerning which engineers differ. Much could be said regarding the advisability of laying certain pavements on certain streets under certain conditions, but these points are pretty well understood as a general proposition, and there is not much question as to which material should be laid to accomplish certain results.

Stone Pavements

Size of Blocks.—While with different kinds of stone some little variation might be made in the permissible size of blocks, as granite is the kind of stone most generally in use, that will be considered here.

It seems strange, with the many societies for standardizing paving specifications and the close interrelationship of the different engineers making up these societies, that at the present time the different cities belonging to these organizations should not use blocks of the same size. For instance, take the cities of New York, Philadelphia, Boston and Chicago, all of which have had members in these various societies. No two of them specify granite blocks of exactly the same size, and the difference between them is so small that the blocks themselves would not be materially different if any one specification were used. But they vary a quarter of an inch here and a quarter of an inch there, just enough to prevent them being alike, and make it impossible for the quarrymen to manufacture blocks and have them all fulfil the specifications of all the large cities using them. If this difference in size is so small that it does not make any material difference in the blocks themselves, it may be thought that there is no necessity for uniformity; but, as has been intimated, if exactly the same size can be used in the different cities, the granite men can make up blocks during the winter season with the knowledge that no matter if Boston does not use as many as usual during the following season, if New York uses more, there will be just as good sale for them as if the usual amount were used in both cities. In other words, if ten million blocks are to be used in 1916, with the specifications for size the same in the principal cities, it does not make any difference to the manufacturer of the blocks just where they are to be used. This is important to the consumers, as they are often obliged to wait after contracts are let for the delivery of blocks, where, if the stock were on hand, they could be obtained without delay.

If, for instance, the sizes of the blocks could be specified as 3½ to 5½ inches wide, 5 inches deep, and 8 to 10 inches long, allowing proper variations, they would comply with the requirements of the different cities as to service and would be much more satisfactory to the manufacturer, and thus cheapen the price of the blocks.

When the oblong granite blocks were first used they were laid on a sand foundation and a variation of 1 inch allowed in the depth; that is, they were permitted to be anywhere from 7 to 8 inches in depth. When concrete was substituted for sand as a foundation, for many years there was no change made in the depth of the block itself, and it is only quite recently that it has been recognized that, as the actual wear on top of the block is very little, a block 5 inches in depth, or even 4 inches in depth, under certain conditions, would be just as good as a 7-inch or an 8-inch block.

Joint Filling.—The old blocks were laid with a joint of at least ¾ inch and sometimes 1 inch in width. These joints were filled with gravel and the interstices in the gravel filled with paving pitch composed of 100 pounds of coal tar pitch and 20 pounds of asphalt. The result was that the blocks wore off on the edges, becoming round and the pavement rough, before the blocks themselves had suffered any material wear as to depth. With the smaller blocks previously referred to, it is possible to have them so dressed without much extra cost that they can be laid with smaller joints and a more satisfactory filler used. In some cases Portland cement grout has been used for filler; in others, coal tar pitch or some asphaltic compound, and sometimes a mixture of coal tar pitch and sand.

Portland Cement Filler

The Portland cement filler gives a very smooth and satisfactory surface. It allows the blocks to be used somewhat rougher on the sides, as the grout, being so thin, readily runs in and fills up all small spaces. It makes a continuous pavement, both longitudinally and laterally, and if the grouting is well done it probably gives a pavement that will stand more actual wear than that of any other filler. On the other hand it makes an extremely noisy pavement. Noisiness is the most objectionable feature in a granite pavement. The wheels come directly upon the blocks, and, as a vehicle rolls from one end of a street to the other, there is carried along with it a noise and a reverberation that is the accumulation of the noise from the different blocks transmitted through the cement joints to the next blocks, and so on until it is lost in the distance. Also, it is an extremely expensive pavement to tear up for the purpose of making repairs to old or laying new subsurface work. It may be said that this is not an objection to the pavement itself. This is undoubtedly true, but it must be recognized that openings must be made in pavements, and if a pavement cannot be easily and satisfactorily restored after it has been opened, this fact certainly militates against the pavement. It is extremely difficult, especially in a well-travelled street, to repair cuts and keep traffic off the new pavement when it has been repaired with cement grouting until the cement has set.

With a pitch filler the difficulty is to get a material that will not be soft enough to run in summer weather or hard enough to be brittle and crumble in cold weather. A proper combination can and undoubtedly will be worked out to meet this objection, except in most extreme climates. The combination of pitch and sand was probably first used in Liverpool, and this

* Consulting Engineer Borough of Brooklyn, New York City, before Worcester Good Roads Convention.

gives a much tougher mixture than when the pitch is used alone. This combination has been used to some extent in this country, and, in the opinion of the writer, will prove a success.

Cushion.—When the concrete base first came into general use, with the blocks 7 and 8 inches deep, it was necessary to have at least 2 inches of sand on the surface of the concrete as a cushion for the blocks, so that an 8-inch block would have at least 1 inch underneath and the blocks would be firm and have a solid bearing and consequently not have undue pressure from the traffic; but when the smaller blocks are used, with a variation of ¼ inch only in depth, it is not necessary to have so great a depth, and the least amount that will give the block a resilient cushion is all that is desirable. This, with the new blocks, should not be more than ¾ of an inch, or, at the outside, 1 inch in depth.

Practically all stone blocks laid up to the present time have been laid on a sand cushion. There is, however, at the present time a discussion going on to a certain extent in the technical press and among engineers as to the advisability of using a mortar bed for stone blocks. If this be done, the whole pavement, including the foundation, will be practically one piece of masonry construction and extremely solid, so solid in fact that the wear under traffic will be more than if it were resilient. If the pavement itself has a cement filler, and so becomes a monolith, this objection is not so great, but the more solid a stone pavement is the more noisy will it be and the greater its wear.

If a cheap cushion could be made of some resilient material, say a combination of certain bitumens with sand or stone, the writer thinks it would be much more satisfactory than a mortar bed. As has been said, the greatest objection to a granite pavement is its noisiness, and if each individual block can be segregated so that a resilient substance will separate it from every other block or the foundation itself, a pavement the least noisy of all can be obtained. If, for instance, stone blocks could rest on an India rubber cushion with the spaces between the blocks filled with India rubber, the pavement would be resilient, as quiet as possible, and, on account of its resiliency, show the least wear under traffic. While it is undoubtedly impossible to obtain such a condition, it can be approached by filling the joints and the spaces under the blocks with some bituminous material that will have as many as possible of the qualities of India rubber.

Brick Pavements

There is very little difference in the opinions of engineers as regards the construction of brick pavements. All the arguments made regarding the different practices of construction of a stone pavement will apply to a great extent to the brick. There will undoubtedly always be advocates of cement as well as bituminous joints for brick pavements, and recently there has been the same discussion about the cushion as referred to for the stone. The writer feels, however, that the conclusions with regard to stone pavements will hold good as to brick, and believes that a better result will be obtained with the sand cushion than with the mortar bed.

The principal argument against the sand cushion seems to be that it is liable to wash out from under the blocks, thus causing a settlement in the pavement. The writer feels that the chance of this is very small and that it need not be considered.

Wood Pavement

It is here that there is probably more disparity in the ideas and practices of the engineers than in any other kind of pavement. This is true because treated wood block pavement is a complicated structure, and it has been in use a shorter time than the other standard pavements. In the early wood pavements the blocks were untreated, and for that reason it was thought impossible for many years to lay a wood pavement that would be satisfactory. But the treated wood pavements of Europe showed that properly prepared wood was a good paving material, and consequently the industry sprang up in this country.

The first thing so consider is the character of the wood itself. It is generally recognized that long leaf yellow pine is the best material. This, however, is an expensive wood and obtained only in certain sections of the country, and if other woods that are more general in their growth can be used after proper treatment and under certain conditions, the cost of the pavement will be very materially reduced. The Government has been making experiments to determine this, and it is hoped that a satisfactory solution will be reached.

There is very little disagreement regarding the size of the block.s They are generally 3 or 4 inches in width and 3½ to 4 inches deep, and average about 8 inches long.

Treatment of Blocks

The treatment of the blocks, however, is the most important. Blocks have been treated with what is known as the zinc process, and the writer saw some in Brussels, in 1913, being laid on the Waterloo Boulevard that had been treated with sulphate of copper, but to a very slight extent. In this country, and probably in Europe as well, it is generally considered that the best preservative is creosote oil. Creosote oil is now manufactured from both coal tar and water gas tar; the former material has been used to the greatest extent and has given satisfactory results. The proponents of the use of the latter contend that it is as good as the coal tar oil. The experience with the water gas oil, however, at the present time has not been such, in the judgment of most engineers, to make this conclusion positive. Experiments should be carried out to demonstrate the usefulness of the water gas oil, as wherever possible the greatest competition should be allowed to all materials. If the oil from the water gas tar is as good a preservative as that made from the coal gas tar, it should be known and used in open competition with the coal gas tar oil.

Whatever oil is used there is always the question of its character and the amount to be used per cubic foot of wood. As regards the character, the principal difference has been as to the specific gravity. Certain people claim that an oil of a gravity of practically 1.03 should be used, and others an oil of at least 1.08 and preferably 1.10. The advocates of the lighter oil contend that it is less expensive, and that on account of its lower specific gravity it will penetrate more freely into the pores of the wood and thus give a more uniform treatment. The advocates of the heavy oil, however, claim that with proper methods of treatment the blocks can be thoroughly impregnated with the heavy oil and that, because its specific gravity is greater, it will be retained in the block for a much longer period of time and so prolong the life of the block correspondingly.

It must be understood in this connection that the object of the treatment is not only to preserve the blocks from decay but also to increase their stability as to size, so that they will not expand in wet weather, thus causing bulging of the pavement, or shrink in dry weather, thus causing the blocks to become loose. The writer has always believed that the life of a wood pavement in most American cities will depend upon the length of time that the blocks will last without decay; in other words, that it will rot out before it will wear out, and the treatment that will for the longest time prevent the block from decaying will be correspondingly valuable.

A piece of wood pavement taken up in Brooklyn after it had been in use for eleven years, on a fairly heavy traffic street, showed a wear of only one-quarter of an inch; so that, assuming that the blocks could stand a wear of one inch before becoming too rough for use and that the blocks would not decay, that pavement would have a life of 44 years. It would seem to the writer that an oil of heavy gravity would preserve the blocks for a longer time than one that was lighter.

The same argument would seem to hold good as regards the amount of treatment to be used. In Europe the general practice is to use about 10 pounds of oil per cubic foot. There, however, as a rule the pavements wear out before they rot out, on account of the much heavier traffic that comes upon them. In Paris and London wood is laid on the heavy traffic streets. One reason for this is because the pavement is so nearly noiseless.

How Much Oil?

The early practice in this country was to use 20 pounds of oil per cubic foot. This practice to a number of people has seemed to be excessive, and the quantity has been reduced to 16 pounds and sometimes to 14 pounds per cubic foot. If 16 pounds is sufficient, it is a waste of money to use 20 pounds, but if 20 pounds will prolong the life of the pavement more than sufficiently to pay for the extra cost of the 4 pounds per cubic foot it should be used. It will undoubtedly take some time to demonstrate what is the proper amount under different conditions. It can be said, however, as a general principle, that the heavy traffic streets will not require as much treatment per cubic foot as the light traffic streets.

It is also argued against the larger amount of oil that the pavements are more liable to "bleed", that is to cause the treatment to exude upon the surface of the street, than if the smaller quantity is used.

Joint Filling.—There is also considerable variation in the use of joint filling, the materials being cement grout, pitch, and sand. The same arguments can be used as regards the filling as with the stone blocks generally, except that sand is not considered permissible under any conditions in stone or brick pavements. The idea is to protect, by the filler, the edges of the stone or brick from undue wear. As the edges of the wood blocks are smaller than in either stone or brick, and as the wood is tougher than the stone or brick, this joint is not so important.

The Use of Pitch

One argument against the use of pitch is that when the blocks expand the pitch is apt to be crowded out upon the surface of the street, thus adding to the nuisance of the bleeding, but, on the other hand, it is urged that when pitch is in each joint, these joints each become an expansion joint and so lessen the liability of the bulging of the pavement. Where there is a reasonable amount of traffic the writer believes that the best results will be obtained by the use of fine, dry sand.

Cushion.—Two kinds of cushion have been in use in wood pavement, one a mortar bed consisting of one part of cement to three or four parts of sand, and the other of sand. The objection to the mortar bed for wood blocks is less than for stone or brick, because the wood itself is a resilient material, so even if the bed is solid, it does not present a solid construction. The writer believes that a smoother surface can be maintained with a mortar bed than with the sand cushion. In Europe the blocks are laid directly upon the concrete foundation. This, however, necessitates the concrete having so smooth a surface that the blocks will bear evenly upon it. As gravel is used in Europe almost entirely for the concrete foundation for pavements, this result is more easily obtainable than it would be with the broken stone in this country. It would entail considerable expense to have the concrete foundation struck to the smooth surface that would be necessary if no cushion were used, and it would seem that almost the same results can be obtained by the mortar bed. Sometimes, however, in Europe a coat of bitumen is spread over the concrete before the blocks are laid. This, however, is for the purpose of keeping moisture out of the bottom of the blocks rather than to serve as a cushion for the blocks themselves, as it is not sufficiently thick to serve as a cushion.

Bituminous Pavements

While some years ago coal tar was used to quite an extent in bituminous pavements, and is now to a less degree, the principal bituminous pavements are being laid with asphalt.

Sheet Asphalt.—When sheet asphalt pavements were first constructed they were laid in two courses—a half-inch course laid first upon the base and rolled, and the wearing surface laid upon that. This was not successful, and what was known as the binder course was substituted for the cushion coat. This consisted of broken stone ranging in size from 1 inch downward, mixed with asphalt, the stone being entirely free from dust. This was used for a number of years but under heavy traffic the wearing surface was driven down into the interstices of the broken stone so that the surface became somewhat rough. To obviate that, what is known as the close binder was laid. A certain amount of dust was allowed in the stone, and, where necessary sand was mixed with it so that the interstices in the stone should be practically all filled, thus preventing any spaces being left for the wearing surface to be crowded into. This has been in use for some years and is successful for heavy traffic streets. The danger in its use is that it may become so smooth that the wearing surface will not form a close bond with it.

Asphalt pavements have been practically standardized, the most important object being the asphalt itself. In the early days it was considered that only the natural asphalts were suitable for pavements, but as the industry expanded the chemists obtained a greater knowledge of the material, so that now it is possible to write a specification for asphalt that is practically sure of obtaining good material, and most cities receive bids on definite specifications for asphalt without regard to its source.

In this connection it might be said that there is some discussion as to the advisability of removing the guarantee from asphalt pavements. When asphalt pavements were first introduced, in order to have the people know that there should be no additional expense to maintain the pavement for a certain period, the contractors guaranteed to keep the pavement in good repair for five years without any extra expense. This period of five years was arbitrary, but has generally been continued. With the knowledge of asphalt that has been obtained at the present time it does seem proper to consider the advisability of it, although the writer would not advocate the abolition of the guarantee just now.

Asphalt Block Pavement.—This pavement has practically been standardized, both in the construction of the block and in the laying. The blocks have been reduced in size materially from the early construction and improved very much in quality on account of the changes in the bitumens. The early blocks were more brittle than the ones used at present, and consequently crumbled somewhat under traffic.

The blocks are laid on a mortar bed placed upon the concrete foundation, and, as the blocks themselves are resilient, it seems proper that they should be laid on a solid base. The object of the mortar bed is of course the same as with the wood—to give the blocks a firm and even bearing.

Bitulithic Pavement.—Another form of bituminous pavement is what is known as "bitulithic" or "Warrenite", a patented pavement that has come into use during the last ten or fifteen years and has been very satisfactory. It is somewhat of the same nature as the sheet asphalt pavement, except that the aggregate consists of stones of about one inch in diameter graded down to dust in a predetermined way so that the voids shall not exceed 20 per cent. This pavement has been used much more largely than any other kind of bituminous pavement except the sheet asphalt. It has been used to a great extent for resurfacing roads that had been improved with waterbound macadam.

Maintenance and Repairs

The American people have never appreciated the importance of keeping street pavements in good repair. The same statement is true of almost all public work. They have had too much the idea that a structure once completed needs no further attention. As a matter of fact all structures need constant care and repairs. This is especially true of street pavements. In fact, no city should contemplate the building of street pavements unless they also propose to keep them in good repair. Just what it will cost to do this is uncertain. American cities, in the first place, have not kept their streets in good condition, but have spent what money they have had in making repairs. Then, too, what money has been spent has not been accounted for in a way that the cost of each street can be known. The standard of good repairs is also different in different cities, and the cost of repairing streets will vary in accordance with that standard, as the better repair a street is kept in the less it will cost. This statement assumes that all of the streets will be kept in good condition, and not a few, so that traffic will distribute itself naturally over the shortest and easiest routes, rather than those which are the best paved. It also makes a great difference if the streets of a city are paved with the proper material. It is manifest that if a heavy traffic street is paved with asphalt the repairs will be much greater than if it is paved with granite, and if a residential street is paved with granite the repairs will be practically nothing for a long time. If, for instance, half of the streets of a city that should be paved with stone are paved with asphalt, the total cost of keeping the asphalt pavements of that city in repair will be much more than if only those are paved with asphalt that should be so paved.

The question, too, of paying for pavements will have some bearing upon repairs. In most, if not all, of the New England cities, pavements, both original and repaving work, are paid for out of the general fund of the city, while in New York the original pavement, and in most Western cities all pavements, are paid for by assessment upon the property owners. As has been intimated, the proper function of a city, as regards pavements, is not to pave the streets once, but to keep them paved, and the word "maintenance", as distinguished from "repairs", means the continuity of a pavement on a street, while "repairs" means simply the work necessary to be done to keep the pavement in good condition from year to year. Maintenance is the more comprehensive word and in this particular instance the greater includes the less.

In order to maintain the streets of a city in good condition and in an economical way there should be established what is known as a street improvement fund, a fund that should be continuously carried over from year to year, so that money saved in one year would be available the next. This, it seems to the writer, is so important that every city should have the right to levy a tax of a certain amount each year for the maintenance of pavements, in the same way as many cities have the power to levy a tax for school purposes. The condition of the street is extremely important in every well regulated city, and the city officials should have funds provided in sufficient amount to keep them in good condition. It is important that the fund should be continuous from year to year in order that the streets be considered as a whole, making it possible to use the money independently, expending a large or a small sum as may be necessary on any particular street to continue the pavement. When repairs are paid for out of one fund and repaving out of another this is not always possible. While it might not be practicable to adapt this principle to the needs of cities where work is done out of separate funds, still if the principle be recognized a great deal of benefit may be derived from it even under adverse conditions.

Operating 45 Plants

The Dunn Wire-Cut Lug Brick Company of Conneaut, Ohio, has had two prominent additions to its family of licensees, the Burton-Townsend Company, of Zanesville, O., with two plants and a present daily capacity of 160,000 pavers, and The Trimble Paving Brick Company of Dayton, O., with one plant at Trimble, O., and another at Gloucester, O. These two companies are among the largest and most prosperous in Ohio. In addition, the Deckman-Duty Brick Company of Cleveland, O., another Dunn licensee, has consolidated with the Wooster Shale Brick Company of Wooster, O., under the name of the Medal Paving Brick Company. This adds one more plant to the three which the Deckman-Duty company owned—one at Cleveland, O., one at Carrollton, O., one at Malvern, O. These accessions give the Dunn company 28 licensees, operating 45 plants.

The Thompson Starrett Co., who have the general contract for the erection of the Imperial Oil Company's new building at Church and Court Streets, have opened an office at room 614 Excelsior Life Building, Toronto.

Progress on Rogers Pass Tunnel

Speed the main factor due to the enormous expense involved and the increasing demand by the enlarged railway traffic—Methods employed—Record speed attained

By J. G. Sullivan*

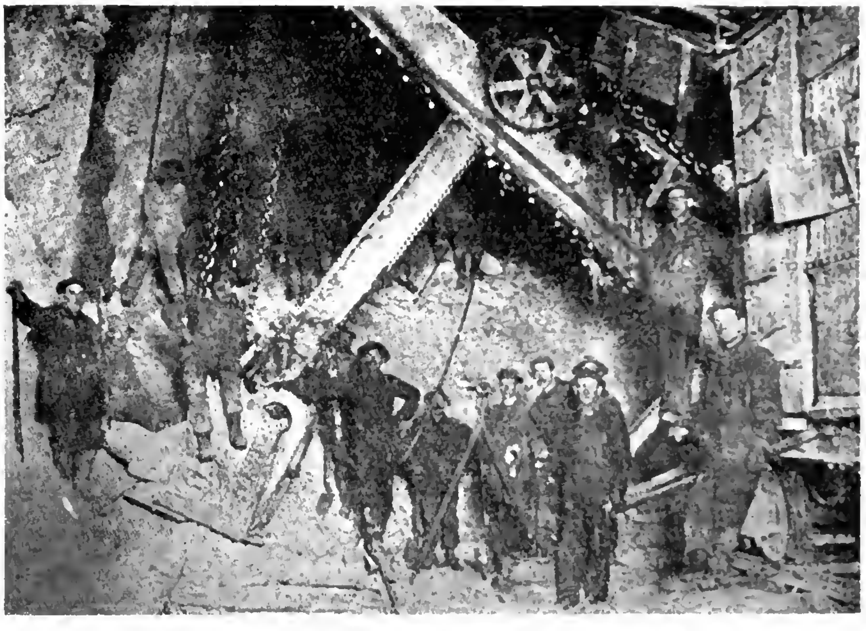
On December 20th, the east and west headings of the Rogers Pass tunnel, the new five-mile double-tracked tunnel of the Canadian Pacific Railway, were joined. The construction of this tunnel through Mount Macdonald, in the Selkirk Mountains, lowers the present high-level summit of the railway grade 552 feet, shortens the distance by 4.3 miles, eliminates some 2300 degs. or 2400 degs. of curvature, and avoids the expense and danger of maintaining and operating 4.5 miles of snow sheds.

In order that the plan adopted in the construction of this tunnel may be properly understood, it is thought advisable to go somewhat into the history of the case. During the period from 1910 to 1913 the traffic on the C. P. R. was increasing so rapidly that it was self-evident that, to be able to handle this traffic if the rate of increase continued, the road would have to be double tracked, in fact a very prominent consulting engineer who reported favorably on the recommendation of the construction of this tunnel, suggested further that it might be necessary to double track the present line over this mountain, gauntleting the heavy bridges, to handle the traffic during the time that might be required to construct this tunnel. The writer knew that tunnels in Europe had been driven at a rate two or three times as fast as any long tunnel had ever been driven on this continent, and in a superficial way had an idea of the methods employed. In a circular letter sent out to contractors dated April 8, 1913, the following statements appeared:

"The necessity for this tunnel is so great and the expenditure so large that it would be worth considerable money to this company to have the tunnel completed as soon as possible. Therefore, everything else being equal, the party who will guarantee completion in the shortest time will be the party who will receive the work. I would be glad if you would give us prices on the European method of tunnelling, which is to drive a very small heading and take out the bench, working from several headings into this small drift. Tunnels in Europe have been driven by this method at two or three times the speed that any tunnel was driven in the United States or Canada, and I would like to be able to place before the management figures for doing this work according to this method. I would be glad if you would state in your proposal the amount per day that you would be willing to have inserted in a contract to be paid as a bonus for time saved over the agreed time, the same amount to be exacted as a penalty for the time lost, being the time between the fixed day of completion and the actual date of completion. We are of the opinion that this sum should be about $750 per day."

The writer, however, was aware that at this time, the chances of American contractors tendering a reasonable figure on the European methods were very remote, in fact, after having studied some of the prices paid for labor in some of the large Swiss and Italian tunnels we were forced to the conclusion that theirs was not a practicable method for this country, where labor is so expensive. On March 15, 1913, the writer reported to the management his ideas on this subject. To quote from the report:

"Referring to the progress that we hope to make in the driving of Rogers Pass Tunnel, I advised you in my report of October 22 regarding the relative speeds of driving tunnels on the American Continent compared with those that have been driven through the Alps. I have given the matter considerable study since, and have come to the conclusion that the European method of driving a small lower heading and stoping out the remainder of the tunnel is too expensive on this side on account of the difference in the cost of labor. I have been thinking out and studying methods



Steam Shovel averages 50 ft. a day in enlarging Rogers Pass Tunnel

* Chief Engineer C. P. R., Winnipeg.—From a paper before Montreal Branch C. S. C. E.

that would tend to expedite this work. I first thought of driving a heading in the centre of the tunnel about 9 feet by 12 feet and keeping this heading close to the bench, carrying the air pipes over the muck in front of the steam shovel and into this heading. I still believe that this method in rock that will stand is better than an upper heading. Mr. A. C. Dennis, however,

Main Heading Rogers Pass Tunnel—Steam Shovel on standard gauge track at work

suggested driving a pioneer tunnel and taking out an upper heading through shafts into this tunnel, taking out the rest of the bench with steam shovels. I pointed out to him that this was impracticable for the reason that from an upper heading you cannot drill to the bottom of the tunnel, and therefore would have to clean up all the muck in the bench before you could put in a round of breast holes to break more rock. I have now made plans showing a combination of my ideas and Mr. Dennis', which, I think, is well worth studying. The plan is to drive a small working pioneer tunnel 8 feet by 8 feet underneath the main tunnel. I am sending you this for your information, and further, if this method should be adopted, that Mr. A. C. Dennis may have the proper credit for first suggesting a pioneer tunnel."

The principles that have been carried out in the construction of the tunnel are, that a pioneer tunnel is driven entirely outside the regular section of the tunnel, and a centre heading is driven in the centre of the main tunnel. The function of the pioneer tunnel is to provide a means of transporting the material from the heading to a point back of where the enlargement of the tunnel takes place, also to provide for the carrying of high pressure air pipes, water pipes, ventilating, suction pipes, etc. In other words, to provide a means so that the shooting at any point in the tunnel will not interfere with operations at other points. The idea of carrying the drills on a horizontal shaft held in place by heavy jacks was to enable these shafts and drills to be carried on narrow gauge tracks and moved backwards and forwards as required, having in mind that heavy drills, as have been used in the past, would be required. As a matter of fact, the Leyner drills used are so light that one man can handle the drill. The result has been that all drilling in the enlargement has been done from vertical shafts.

The pioneer tunnel at the east end is located 50 feet to the north of the centre line of the main tunnel, and the pioneer tunnel at the west end is 50 feet south of the centre line of the main tunnel. The mode of operation is as follows:—the drilling in the small headings is done in the usual manner, using in general Leyner drills, making an advance of 6 or 7 feet for each round of holes. The muck is shovelled by hand from steel plates into half yard cars and hauled back, either by a mule or small compressed air locomotives, the latter being used after the haul got to be a considerable distance. The muck from the headings is carried out through cross-cuts into the pioneer tunnel, where it is carried back to a cross-cut, and there carried out on a trestle over the standard gauge tracks in the main tunnel and dumped into standard gauge cars, from which point it is removed to the fills in a similar manner to the muck loaded by steam shovels in the enlargement. The muck from the heading on the west end in a similar manner goes into the pioneer tunnel at a cross-cut, crosses back to the main tunnel in a cross-cut, where it is dumped into standard gauge cars. In the enlargement of the main tunnel the drilling is done well ahead of the shooting. At first the radial holes were drilled at right angles to the axis of the tunnel. This did not give the best results, and it was changed to a drilling showing an inclination of about one in four away from the direction in which the tunnel is being driven. The muck is all loaded by steam shovels into standard gauge 12-yard capacity dump cars. The shovels have dippers of 1½ cu. yds. capacity and are worked by compressed air. The cars are hauled to the mouth of the tunnel by standard gauge compressed air locomotives and from there by standard steam locomotives.

The contract for this work was let on July 1, 1913. The limit of time for completion was three and one-half years, which would bring the time to January 1, 1917. There was an allowance in extension of time of one day for every 10 feet of soft ground that was encountered, which would require immediate timbering. There was in the neighborhood of 1,660 feet of such ground, which would extend the time limit of

Final connection of the Pioneer Tunnel—Looking west

the contract to some time in June, 1917. There was driven to December 19, 1915, 19,610 feet of pioneer tunnel; 24,612 ft. of centre heading; 1,660 ft. of earth tunnel, and 14,342 ft. of tunnel enlargement in rock. There remains to be driven: 288 ft. of centre heading; 19,398 ft. of tunnel enlargement. The best progress in driving pioneer tunnel heading was 932 ft. in one heading in the month of January, 1915, west pioneer. The best record for a week of enlargement was 267 ft. The best progress to date for a month of enlargement was 827 feet for the month of August, 1915, west end.

From April 1st, 1915, to December 19, 1915, 12,346 feet of tunnel enlargement has been made. This is about the time that the shovels were both working in rock and were working at a normal rate of speed. This same rate would require a little over seven months in which to complete the tunnel. There will, however, be some slowing up in the enlargement between certain cross-cuts which are at the end of the pioneer tunnels for the reason that at present fans are installed at the mouth of the pioneer tunnel at each end. Doors are put in the cross-cuts between the pioneer and the centre heading. All of these doors are kept closed back of the shovel, and when shooting takes place in the enlargement of the tunnel the door at the first cross-cut beyond point of shooting is opened. This creates a very strong draught back over a pile of freshly shot muck and makes conditions such that the men can return to work in ten or fifteen minutes after a shot. The shooting of the muck in the enlargement of the main tunnel is done in the following manner: one round of holes is shot at a time, the holes in the bottom of the tunnel being shot in advance of the holes on the sides or on top. In some cases the top holes are not shot until all of the bottom holes have been shot out. Usually six or seven rounds of holes are shot before the steam shovel starts cleaning up the muck, that is, a distance of 30 ft. to 35 ft. The shooting is generally continued until the tunnel becomes so full of muck that no more shooting can be done. The largest amount that was ever shot at one time was on November 20, 1915, when 84 feet was shot in eleven hours.

I may say in conclusion that all our expectations as to speed have been more than realized, and that for any rock tunnel where the rock is of sufficient hardness to stand until after the mucking has been done, that this method can be worked successfully and a speed of three miles per year can easily be made at a much less cost than tunnels driven at the same speed by the European method; and furthermore, the radial shooting has proven that a great deal less over break can be expected from this method than where holes are put in parallel with the axis of the tunnel.

This work was laid out and started under Mr. F. F. Busteed, engineer in charge of double tracking, with Mr. J. W. Shepperd as assistant engineer, and has later been carried out under the supervision of Mr. W. A. James, engineer of construction, Western lines, with Mr. H. G. Barber as assistant engineer; Mr. T. Martin as resident engineer, at the west end, and Mr. J. R. C. Macredie as resident engineer at the east end. The contractors are Messrs. Foley Bros., Welch and Stewart, construction work being supervised and managed by Mr. A. C. Dennis, superintendent for the contractors.

Canadian National Clay Products

Successful Convention of Clay Products Association at King Edward, Toronto—Good attendance and lively discussions.

The 14th annual convention of the Canadian National Clay Products Association was held at the King Edward Hotel, Toronto, on January 18, 19 and 20. Keen interest was taken in the convention as a result of the present situation in the building trades and the lack of demand for brick at the present time. About 120 delegates assembled from different parts of the Dominion. Mr. J. E. Frid, president, occupied the chair. The papers presented covered a wide range, from the various steps in the mining, storing and manufacture of clay and clay products to the best methods in selling the different products.

The Convention was opened with an address of welcome by President J. E. Frid, of the George Frid Brick Company, Limited, Hamilton, followed by an official welcome on behalf of the city of Toronto by Mayor Church. Mr. Joseph Russell, M.P.P., Toronto, replied on behalf of the delegates. Mr. D. A. Lochrie extended a welcome to the Convention on behalf of the Entertainment Committee, and Mr. Hubert Desjardins, of the Montreal Terra Cotta Company, Limited, Montreal, replied.

After the secretary-treasurer's report and the report of meetings, Hamilton was chosen as the place for the next convention. The election of officers resulted as follows: President, J. E. Frid, Hamilton; first vice-president, A. F. Greaves-Walker, superintendent Sun Brick Company, Toronto; second vice-president, Mr Thomas Kennedy, Dominion Sewer Pipe Co.; third vice-president, William Burgess, Don Valley Brick Company; secretary-treasurer, Gordon C. Keith, Toronto; councillors, C. B. Lewis, Milton; A. Graham, Toronto; W. Clark; R. N. New; H. Desjardins; A. Neall; D. A. Lochrie and J. S. McCannell.

Wednesday Session

At the morning session on Wednesday the chief items of business were the delivery of three very instructive papers and their subsequent discussion. Mr William Burgess, Superintendent of the Don Valley Brick Works, Todmorden, gave an interesting paper on "Operating Clay and Shale Pits in Canada." An instructive article on "Brick" was delivered by J. P. Hynes, of Hynes, Feldman & Watson, architects, Toronto, and Mr. Joseph Keele, of the Mines Branch, Ottawa, followed with a paper on the "Application of Salt and Quicklime in Drying Clay Products." Mr. Keele gave particular attention to the clays of the western provinces, where the difficulty of clay products cracking while drying has been very troublesome. This cracking is due to the constitution of the clays. Some clays when worked have a soapy, sticky feeling and contain large proportions of dilatinous matter and very little lime, and the surface dries so rapidly that the interior remains a soggy mass, resulting in cracks. The Mines Branch, Ottawa, have carried on extensive experiments to find some means whereby the western clays may be made into products in demand, at a reasonable cost without materially weakening or destroying any valuable properties brick should possess. Preheating might prove beneficial but its cost in Canada makes it prohibitive, when other manufacturers are selling brick at a low figure. The use of chemicals was tried. Sodium carbonate, while it aided drying, did not materially affect the stickiness. Lime also aided the drying process, but an excess of lime in the burning destroyed the red color due to the iron, giving the brick a buff color. Discussing whether washing would not remove the dilatinous material, Mr. Keele said experiments showed that washing removed 75 per cent. of the clay and left a residue which was still sticky.

Wednesday Afternoon

The afternoon session opened with an address by W. W. Pearse, city architect, Toronto. Mr. Pearse expressed his thanks to the clay workers for the hearty support given him recently in compiling data on bricks—preparatory to a revision of the building by-laws of the city of Toronto. Mr. Pearse pointed out that information or necessary data on building materials based on tests were extremely difficult to get, and in fact were practically unobtainable for Canadian materials. Such information as was procurable was based on tests made in the United States on American materials and under climatic conditions different from those in Canada. The aid of the government is needed to establish bureaus where such tests can be carried out with Canadian materials and the data compiled for the use of all municipalities requiring them. Mr. Pearse then outlined the methods used and the results obtained in the brick tests recently carried out under his supervision. Three bricks were taken, not necessarily selected, from each yard. One brick was planed to a smooth surface so that the distribution of the load would be uniform—placed on supports 7 inches apart and a crushing load applied. The modulus of rupture or fibre stress was obtained, also the bending stress and an absorption test made. It was found that neither the absorption nor the bending stress had anything to do with the crushing stress. Mr. Pearse pointed out that after careful investigation he had been able to classify the various qualities of brick manufactured in Toronto and he stated that the brick made here was as good, if not better, than that made in the States. "Bricks made in Toronto are classified into three groups," said Mr. Pearse, "A., B. and C. The first class of brick is considered the best brick, and when a certain class of building is to be erected in this city we call for this class. The second is just a little inferior and would be good for buildings which would not call for Class A. And the last, Class C., would be used only on one class of building. By this means we will know exactly what class of brick will be used in each building, and after the tests that have been made I am certain that the buildings will be better."

Mr. J. E. Frid, Hamilton, President of the Canadian National Clay Products Association, 1915 and 1916

Passed Resolution

Mr. Pearse asked for the co-operation of the clay workers to establish this bureau and would like to see tests carried on under actual conditions, such as in a wall, the effect of eccentric loading and the relative merits of lime and cement mortar in the final strength of the walls. Following the discussion the following resolution was passed:

> "Resolved, that we, the Canadian National Clay Products Association, urge that the Dominion Government, through the Commission of Conservation or other branch of the public service, extend the work they are carrying on at McGill University, Clay Testing Laboratories at Ottawa, etc., so that they can establish a central bureau and supply accurate information on Canadian building materials to all municipalities requiring same."

The need for something of this nature was shown at the inquiry into the causes of the collapse of the chimney at the new gymnasium of the University of Toronto, where no one could testify how much weight green mortar would sustain. The necessity for compiled data on Canadian fireproof material is very pressing and it is high time Canadians had their own data.

Following Mr. Pearse, Mr. A. F. Greaves-Walker, manager of the Sun Brick Company, Toronto, gave a very interesting and detailed paper on "Hollow Ware Dies, Troubles, How to Correct Them." This paper was of especial interest because it is such a vital question to many manufacturers. Dies, whether they be real new ones or have been used before, invariably need adjustment the first time they are used in a new plant. The conditions that govern the working of dies vary so extensively that a die operating very successfully in one plant may refuse to work in another doing similar work. The causes are numerous, but if properly studied can, as a rule, be easily remedied. In round uniform tile dies there is not much difficulty encountered, but with the complication of the parts, the addition of webs, etc., the difficulty of obtaining a uniform flow of clay throughout becomes manifold. Flow will take place along the line of least resistance, and if the sections are not properly balanced a fast flow will take place in the middle or the side, or in some particular web, with the result that the texture is different, and when the product dries it warps or cracks. Whenever possible, correct fast flow by reducing the area at the fast point or put a baffle of iron or wood on the back of the die. This slows up the flow but very materially increases the horsepower necessary to operate the machine. Or, increase the area of the slow flow. The dies are an important factor in the texture of the finished product. Dies are classified as follows: (1) Dry, lubricated, (oil, water and steam); (2) flat, or tapered; (3) face-plate (flat or tapered). Dry dies should be used if possible with flat dies for such wares as drain tile and a tapered or compressing die for fireproof wares.

Other features to consider in eliminating bridge cracks are, the distance of the bridge from the point of issue and the condition of the face of this bridge. Frequently small adjustment of the bridge either way or roughening or polishing the bridge face, will eliminate otherwise troublesome cracks which appear after drying. The size of the grains and the speed of the machine are other factors to consider. A small grain requires a higher speed than a larger grain. Quite often this factor cannot be remedied on account of the use of constant speed steam engines, but with the advent of variable speed electric motors, better results are being obtained. The auger also bears an important relation to the quality of the finished product. Single wing augers, while they give the fastest flow, tend to drive the clay too fast in the centre. This fault is overcome by the use of two-wing augers and still further by the three-wing, which give the most uniform flow. If, after all these factors have been considered, and the product leaves the die in apparently perfect shape, it be not properly dried, it will still develop cracks or warp. Great care should be taken in drying hollow ware products to have it heated uniformly throughout. This is best accomplished by spacing or by blowing warm air up through the wares. Never pack die products close together, and let air sweep over the top because this dries the tops first, sets up a lateral stress in the tile and produces a hair crack completely round the tile, which may not be detected. When the tile is subjected to strain, however, it often falls in two.

The annual banquet was held in the Prince George in the evening. The patriotic spirit was strongly in evidence at this banquet, practically all the speakers referring to the war crisis and Canada's participation in it.

Thursday Session

Mr. Chas. A. Miller, Inspector of Clay Products Plants under the Workmen's Compensation Act, resumed the session on Thursday morning with an address on "Safety in Clay Products Plants." Mr. Miller gave the statistics on accidents during the year 1915. These show that the railroads claim the greatest number of victims, with the iron and steel industry making almost as heavy a toll. In the clay factories of Ontario no fatal accidents occurred, and only about sixty serious cases were reported. Statistics show that the majority of accidents occur in the clay beds, rolls, gears and from cables and set screws. The discussion, which was very spirited, pertained chiefly to the Workmen's Compensation Act, and the effect on the company as well as the workmen. The question of first aid to an injured workman came in for a heavy share. Who should pay the doctor who is called in for first aid? The company are not bound to call him under the Act. All they have to do is send the man home and notify the Board and it may be some time before the Board can adjust the case and pay the victim. In the meantime he might starve. If the company calls a doctor he can come on the company for his fee. This is one item that needs attention, but it was the opinion of the Convention that the Act is a valuable asset and in time will become adjusted to the special conditions and be a very valuable factor for good.

Future of the Face Brick Industry

"The Future of the Face Brick Industry in Canada," by F. R. McCannell, managing director, Milton Pressed Brick Company, Milton, was the next paper and one that just at present is a live item among brick manufacturers. The future of face brick depends on how good a product can be manufactured at as low a cost as possible. Manufacturers should keep an accurate cost system in the plant to see that they are getting the proper amount of work in the different departments for the given expenditure, establish standard methods wherever possible and form a central bureau, employing a competent man to look after credits and collections.

The discussion hinged largely on the relative merits of rough and smooth-face brick. Rough-cut brick, which has been in popular favor for some time, composes about 75 per cent. of the United States face brick. But the death knell of rough-cut brick in the east has been sounded. The fact that it collects dirt overcomes its advantages in color range, and it is not a brick for down-town sections. The trouble in the brick business, especially in the States, is the hobby for something new, different from the last type used. The salesmen advocate a change, the owner calls for something different, and the manufacturer loses money because he cannot use standard methods and manufacture one kind straight ahead.

The paper on "The Clay Deposits of Southern Saskatchewan," was a report on the valuable clays of that district, their occurrence, uses and exploitation, by Mr. N. B. Davis, of the Mines Branch, Ottawa. With the decreasing supply of clays in Ontario and Quebec, attention naturally turns to the western provinces. Have they a supply to fall back on? It is quite evident from Mr. Davis' paper that they have. There is an abundance of refractory clays for stone wares and white wares as well as for burned clay products, in Saskatchewan.

The afternoon session on Thursday was given over principally to a discussion of the business end of clay-working plants. Professor Wiggins, Inspector of boilers, gave the delegates an instructive address on the steam end of a clay-working plant; how to overcome waste, increase the efficiency, and lower overhead charges.

Mr. Greaves-Walker read an instructive paper on "Clay Preparations for Stiff Mud Products," prepared by Prof. Roy T. Stull, ex-director of Ceramics, University of Illinois. A product is no better than the material it is manufactured from. Of course, a poor man may spoil good material, or an expert may make a fairly creditable product from a poor material. In the clay industry, following this idea, great care should be taken from the time the clay is mined till it goes into the machine, to get a uniform grade of texture. Prof. Stull advocates storage. After mining the clay it should be ground, screened and stored so that with a change in climatic conditions no change results in the clay going to the dies. If one part is drier than another, when the ware is made and set out to dry, the drier part absorbs moisture from the wetter portion and causes the ware to expand and necessarily crack or lose strength. The use of storage with an automatic feed is advocated to procure a uniform grade of texture.

Selling Brick

The secretary then read a paper from Mr. L. H. Wiers, of Thompson Brothers, Windsor, on selling brick. Mr. Weir says that to sell brick to advantage one must:

1. Run an advertising notice in the daily papers and change it often.
2. Educate the people on the merits of brick.
3. Never leave a customer dissatisfied, even after all other methods failing, you have to remove your brick for some other.
4. Quote one price to everyone and stand by it.
5. Read every trade journal on brick you can find.
6. Know your own products.
7. Always sell firsts as firsts, and seconds as seconds.
8. Don't get lazy.
9. Know all you can, tell all you can, to everyone you can, about brick.

The question whether to quote one price to every customer brought forward some healthy discussion. The consensus of opinion appeared to be that it was wisest to agree on one price but set different terms, make sure of a prospective buyer's security, tell the truth in all matters, stick to your contract, and in all cases satisfy the customer. Never sell a second for a first. Set a standard and keep to it. The trouble with the brick industry at present is that the buyer knows more about the price than the salesman. You manufacture all right but have poor salesmen. It would be wise when you go for a brick contract to take a brick with you to keep your feet warm. The convention adjourned to meet next year in Hamilton.

The Dearborn Chemical Company of Canada, Limited, presented all delegates with a faced blotter bearing their advertising. Mr. H. E. Hunt gave a six-inch ruler bearing the words "The rule is to have your brick moulds and wheelbarrows manufactured by H. E. Hunt, Toronto." The Federal Engineering Company, Limited, presented all delegates with a small leather-bound vest pocket memorandum book.

Visited Technical School

At four o'clock Tuesday afternoon, on invitation of Dr. A. C. McKay, principal of Toronto Technical School, the clay products manufacturers paid a visit to the new clay products and construction laboratories at the Technical School. Among the different machines inspected with interest were:

A No. 2 Kels machine, complete with 8 ft. x 20 in. end delivery pug mill, hand cutting table, tile, brick and hollow ware dies, supplied by H. C. Baird & Son, Parkhill. The total length of the outfit is about 16 ft., the width about 4 ft., and the height about 4½ ft. Automatic cut-off table, by B. E. Bechtel, Waterloo. Martin brick machine, by the Sun Brick Co., Toronto. Set of Moulds, by H. E. Hunt, Toronto. Firebrick for kiln—Elk Fire Brick Co., Hamilton. Face brick—Don Valley Brick Works, Toronto. Grate—Canadian Steam Boiler Equipment Co., Toronto. Kiln iron—Baines & Peckover, Toronto. A number of clay products manufacturers have supplied samples for the museum building products. In the evening the delegates were the guests of the Entertainment Committee at a theatre party at Shea's Theatre.

Paying the Quantity Surveyor

By William Groves Smith*

The greatest obstacle confronting those engaged in the introduction of the Quantity Survey Method has been the question of payment of the Quantity Surveyor's fee.

Architects appreciate the great assistance a Quantity Surveyor can give.

Contractors are well aware of the heavy expense of taking off quantities on job after job that they do not win.

Everyone in fact who is well informed feels the defects of the customary methods and knows that something ought to be done about it. But how?

Architects cannot afford to pay for a Quantity Surveyor out of their fees.

Contractors cannot agree on a method for dividing estimating cost. Several attempts at Contractors Central Estimating Bureaus have failed.

For a long time the only way seemed to be to have the building Owner pay directly for the Quantity Survey. This is perfectly logical and would be a profitable investment for him. Unfortunately, however, this method of payment demands the Architect's recommendation to the Owner and entails a lot of educational work before the average Owner can understand wherein he will profit by a Survey. Many architects shrink from this task.

We propose the following simple and fair method, as desirable and profitable to all parties.

Our Fee Payment Plan

The architect will decide how many general contractors may bid, say ten.

Divide our fee by ten.

Charge each general contractor that amount for a complete Quantity Survey of all trades.

Each general contractor can collect from his subcontractors the proper amounts for Bills of Quantities in their trades.

In this way each contractor will receive accurate itemized quantities, at a fraction of the expense to which he would be put to take off quantities himself.

Advantages

It leaves control of the whole matter in the hands of the architect.

It saves estimating expense to the contractors.

It assures close, intelligent bids to the Owner's advantage.

Details

The architect has only to instruct his contractors that he will use guaranteed uniform quantities as a basis for bids.

The architect can collect our fee or can instruct the contractors to get the Bills from us at a price agreed upon with the architect.

No change in the usual form of contract is necessary.

We will give an acceptable surety bond guaranteeing the quantities to the successful contractor or to the building owner.

This plan does not alter our policy of giving all the service demanded by the Architect and Owner in the nature of estimates and quantities from the sketch plan period to the completion of the building.

Amount of the Fee

Our fee varies from ¼ per cent. to 1½ per cent., according to the size and character of the job.

* In the Engineering Contractor

Motor-Driven Street Flusher

The increased area of paved city streets and the more general recognition of the necessity of the thorough cleansing of pavements has naturally stimulated the design of street cleaning equipment while the substitution of the gasoline motor for the horse to furnish motive power has made possible the building of machines of this kind of greater capacity and efficiency than was possible under former conditions.

One of the street cleaning machines which have been put on the market recently is the motor-driven street flusher shown in the accompanying illustration.

Briefly described, the flusher consists of a 6-ton motor truck chassis, equipped with a 6-cylinder Continental motor. Mounted on the chassis is a 1,500-gal. water tank and the distributing mechanism which includes an additional gasoline motor and a centrifugal pump for discharging the water under pressure. The pump motor is a 4-cylinder, 20-HP. Continental motor and is located at the rear of the tank. The 2½ in. centrifugal pump is capable of delivering 250 gals. of water per minute at a pressure of 70 lbs. per sq. in. There are four discharge nozzles, one on each side about half way between the front and rear wheels, and one at each side at the front of the machine. The nozzles can be operated singly or in any desired combination, and are so arranged that by driving down the center of the street the entire width of the pavement can be flushed at one operation.

Sprinkling nozzles which are interchangeable with the forward flushing nozzles are also provided, so that the machine can be used for both power flushing and sprinkling and gravity sprinkling.

The pump motor, as well as the motor for driving the truck, is controlled from the operator's seat, the two motors being entirely separate. Any desired water pressure may be maintained reardless of the speed of the vehicle and is one of the chief advantages claimed for the machine.

Another is that the two motor arrangement is more economical as the extra horse power required for operating the pump need not be provided for in the vehicle motor and the flusher motor is in operation only when flushing is being done.

The entire separation of the propelling and water pressure systems also makes it possible to remove the tank and use the chassis for other purposes during that season of the year when street flushing is impractical. Where hydrants are not available for filling the tank, a special attachment can be provided for drawing the water supply from rivers, creeks or other sources.

New Method for Producing Pure Iron

It has been recently announced by the University of Illinois that a new method of producing pure iron, whereby a great saving can be effected in the electrical industries of the country, has been discovered by Trygve Yensen of the experimental bureau of the university. The new method consists in melting electrolytically-refined iron in a vacuum, and this reduces the impurities to a point far below that which has been reached by previous investigators. The magnetic properties of this vacuum-fused iron have proved to be as remarkable as its purity, its maximum permeability being reported to be about 20,000, or about seven times that of the sheet metal commonly used for transformer cores. The practical result of this investigation is obviously that the amount of iron required for the magnetic path in electrical machinery of all kinds can be reduced very materially and the magnetic losses may be largely decreased. It is said that the University of Illinois has declined to permit a patent to be taken out on the process, as it is believed that the benefits from it should accrue to industry as a whole.—Elec. Ry. Journal.

Motor-driven power flusher Flushes entire width of street.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

John Thompson, son of the late Sir John Thompson, is receiving a lot of credit from the Tory press because he not only gave his services gratis as prosecuting attorney with the Davidson Commission but afterwards volunteered for active service at the front. But in this cold world a man is judged not by what he volunteers to do but by what he actually accomplishes. Mr. Thompson conducted the affairs of the commission so well that while one or two minor offenders were mentioned in despatches none of them could in any way be connected with any part of any political machine. He has closed the investigation without discovering anything. It can be truly said that he has conducted one of the most successful investigations in the political history of Canada. But why should he be asked to do all this good work gratis? Is the government of Canada so poor that it must accept volunteer counsel for one of its specially appointed courts? What one gets for nothing is generally worth just what it costs. Anyway who ever heard of a lawyer giving anything, even advice, for nothing? And when Mr. Thompson goes to the front will he go as a private? Or will he carry one of those nicely engraved commissions that so many of our patriotic fellow-countrymen are pulling for?

* * *

The Minister of Militia has asked that "men of standing in business, professional or mechanical life, will send their names to him." He conveys the idea he wants them as officers for he is further quoted as saying "We want to know who is who before we make appointments or permit the raising of any new regiments under new auspices." But naturally the question arises as to whether the Minister means what he says or is simply making a bluff to cover some of the practices that have hitherto governed the appointment of officers. Let me cite an example. A well-to-do financial man of Toronto was anxious to do his bit. His years and experience did not exactly fit him for too heavy work, but in this hour when every man is needed, he thought he might act as paymaster, thus relieving some husky young officer for more active work. He wrote to Ottawa for an appointment and was referred to the officer commanding No. 2 Division. The latter told him his application would receive consideration. Some days later a friend called him aside and told him he would get the appointment but he had first to secure the influence of two Toronto men, local members of the Provincial Parliament. He told the whole bunch to go to Hades—wherever that is.

* * *

Now if Sir Sam was as frank as he is loquacious would he not have wound up his statement with "only those having political influence need apply." For the past has shown that numbers of officers have been chosen not because of their fitness or capacity but for the amount of political pull they can develop. There are hundreds of incapable Canadian officers now stalled in England, so I am told. They may easily be found around the Savoy Hotel in London, having a good time at the expense of the Canadian taxpayer. With rare exceptions the efficient have reached the front. They have helped cover Canada's name with glory. But thank heaven that every officer whose pull and influence secured him an appointment has not been allowed to reach France.

* * *

But why should this sort of thing be permitted in a country that is partially intelligent, more or less free and inclined to be democratic? Why should we be the victims of a party system that is all the more contemptible because it is half hidden under a cloak of hypocrisy? If "to the victor belongs the spoils" is to be the party system of this young country let us be open and above-board about it. Let us not fool ourselves with the idea that government is being carried on by the people for the people but announce to the world that our governing is by the party for the party. In short, if we are to have a patronage system, give us one of the good old Yankee variety, where every office holder pay tithes to the party and knows the costs of a job beforehand. They make no bones about it. This sneaking method of pretending virtue while practising deceit fills us with disgust.

* * *

Canada has now more than a hundred knights—more than could find place at King Arthur's famous round table. She also has a minor aristocracy made up of honorary colonels, etc. And while the wearers are doubtless proud of their titles it is doubtful if even those who have honestly earned them are more respected because of them. There are others of course who hang to a rather precarious fame by the handle their title affords. But great Canadians do not require a title to keep their memory green in the minds of their country; others who have been "honored" by their country or rather by their party, do not receive more respect because they have been hung on a hook a trifle above the democracy that is the backbone of every new country. Sir John A. Macdonald is still "John A." to the men who loved and followed him; Alexander MacKenzie still holds a place in Liberal hearts that will never be attained by many a man who has been "decorated by his King." If titles have any value at all in Canada it is because they foster democracy. The man who refuses a title is a patriot; the man who accepts one is often more or less of a joke.

* * *

The following from the Ottawa Evening Journal of the 10th inst. speaks for itself:

"In talking over the matter, Sir Sam Hughes mentioned that his chief intelligence officer was a Canadian of German birth, whose father was now an officer in the German army, whose mother was the daughter of an Austrian general, and whose brothers were officers in the German army. This officer is described by General Hughes as one of the very best in the Canadian army."

* * *

The suit entered against the heads of the Canadian Northern Railway for the return of money paid for land in Port Mann brings fresh evidence that there are other ways of exploiting the public besides floating loans at Ottawa. When the Grand Trunk Pacific was building, thousands of townsites sprung up ahead of the construction work. There was always the one who knew where the townsite was to be plotted. He informed his friends. They got in early and waited for the rush. Many a man cleaned up a tidy nest egg in this simple way. But according to the allegations against the C. N. R. all rights were reserved so far as Port Mann was concerned. It, a secluded spot on the banks of the Fraser, was to be the Pacific terminus of the greatest transcontinental railway ever built by Canadians with the money of other Canadians. It was surveyed and slashed. One or two streets were even relieved of their stumps. Then lots were sold both wholesale and retail. Lots three-quarters of a mile from the modest wharf brought from $2,000 to $3,000. Everybody in B. C. and a lot of folks besides bought these lots as if they were solid gold. But alas they were only gold bricks. The C. N. R. moved its terminus on to Vancouver, the wind oozed out of the Port Mann boom and that secluded spot on the Fraser resumed its ancient and honorable place as part of British Columbia's matchless scenery. And now some folks are so inconsiderate as to want their money back. So unreasonable of them too.

* * *

The dignified and talented president of the Bank of Commerce has paused for a moment to hand us a little more advice. He tells us we should economize. He doesn't go a step further and tell us to put the money we save by our economy in the bank. Why should he? Any fool knows that the only way to start saving is to open a savings account. And when the bank gets it of course it will help to carry on the war to a successful issue or help to move the crop. Of course it will—or at least that part of it that isn't sent on to New York to be put out on call loans to Yankee stock speculators and stock brokers. Or maybe it is needed to be loaned to Canadian promoters for investment in Brazil and Mexico. When hard times strike this country our banks immediately proceed to economize by refusing business men the necessary funds to carry on legitimate trade. Does the money they refuse lie idle for that reason? Well, not according to the annual bank reports.

* * *

The same government which pays 5½ per cent. interest on war bonds keeps the rate of interest on post office savings at 3 per cent. Does said government wish to convey the impression that its bonds are twice as great a risk as money in the post office, or is it merely trying to create a market by offering bonds at bargain prices? Surely the government wants the people to save. Why not pay them a more attractive rate of interest till they have saved enough to invest in bonds? Why not encourage thrift among our people?

* * *

Will the Minister of Militia deny that he is directly or indirectly financially interested in the Ross Rifle Company?

* * *

The Shell Committee, its alleged crimes and self-asserted virtues, has been brought before Parliament by Dr. Pugsley, a Liberal statesman who has probably been taught that he who is without sin should throw the first stone. It is to be regretted that what should be only a business proposition is thus being made more and more of a political question. It is unfortunate that Sir Robert Borden failed to listen to the voice of the more independent of the Conservative press and order a full and free investigation into the workings of that committee. If there was nothing to hide he had nothing to lose. If there was something to hide a full investigation ordered by himself would free him from all blame and responsibility. Dr. Pugsley has made so many charges, though insignificant in comparison to the real facts, that an investigation should follow and if any or all of the charges are sustained the Government must share responsibility with the Shell Committee and the profiteers. I have felt from the first that such an investigation was necessary for the protection of the manufacturing interests of Canada and with me those interests come before the political welfare of Sir Robert Borden, whom in many ways I admire.

* * *

In a recent issue, concerning shell committee charges, the Montreal Star, (Con.) says:

"In any case, the Government cannot permit these shocking and humilitating charges to remain uninvestigated."

* * *

That the indiscriminate handling of support for soldiers' families is working out badly in both directions is shown in numerous instances. A private in a certain platoon in the — battalion boasts that he is at present drawing $160 per month whereas he never before drew more than $50 per month. He is an employe of the T. Eaton Company, which generously allows him full pay and he gets in on all the funds. On the other hand an acting-sergeant informs me that although he has been at the Exhibition camp for nearly a month his dependents have not received a cent from any source and that even part of his pay has been held back for fear he'll elope with his uniform. Some kinds of patriotism are too profusely fertilized and some are simply starved. But then no British people ever did develop a government that was big enough to handle a war.

* * *

To all appearances the British people have awakened and decided to "get on" with the work. The British papers are warning, mildly as yet, the world not to tread on the lion's tail. The London Standard puts it:

"Germany is now clothed in a white sheet. She and America are joining hands in the noble task of bullying the nation that has respected every law of humanity and has persistently interpreted the law of nations to her own disadvantage.

"Poor England. No moral crime can be laid at our doors, but we are interfering with the war profits of American manufacturers, so we must raise our blockade and thus prolong the war, and this is asked for in the name of humanity.

"There is one comfort for us miserable sinners: President Wilson and Count von Bernstorff will knock at our door in vain."

* * *

The attitude of our Australian cousins towards the munition-making business is in humiliating contrast to the conditions under which this work has been carried on in Canada. Over in Australia, Government and private factories scorn to accept exorbitant "blood" profits at the expense of the lives of their sons and brothers at the front. As an example we may quote the West Australia War Commissions Company, Limited, organized when the war broke out under state supervision by leading public and business men of the state. The whole capital was furnished by public supscription on the understanding that there should be no dividends and that the price of the manufactured articles should be as nearly as could be fixed the actual cost of those articles. It was further stipulated that any profits remaining after the repayment of the paid-up capital after the war should be devoted to patriotic or charitable purposes incidental to the war. The same spirit evidently animates private companies, who have undertaken contracts from the Government at certain named prices on the understanding that if these are greater than the actual cost of production of the article the balance shall be refunded.

In comparison with this truly patriotic attitude Canada merely offers examples of the operations of our late shell committee such as the original letting of contracts at $6.70 per unit which have later been reduced to $1.85; the boasts of our financial magnates of huge war profits; and the scandals attaching to other purchases.

If these men, our leaders, represent Canadian culture, is not the world saying that it at least compares "favorably" with the German type?

* * *

After a long silence the peeved voice of the Opposition Leader is again heard in the land He should be ashamed to criticize the Government, even if they deserve it He has waved the British flag, he has told us what a great Britisher he is, but has failed to live up to it. What is he doing to induce his countrymen to play their part in the cause of freedom? If his is a "soul so dead" that he cannot speak in favor of the British Empire, can he not at least keep those of his own kidney, like Bourassa and Lavergne and Croquette quiet?

* * *

When are we going to get some information concerning the Ross Rifle? Rumors suggest that after the disastrous fight at Langemarck the British Government made a report to Ottawa concerning the rifle. If so, why is this report not made public?

SEARCHLIGHT.

Personal

Mr. A. McKenzie Brydon announces that he has withdrawn from the firm of Lindsay, Brydon & Greig, and has for present address 204 Glencairn Avenue, Toronto.

Mr. H. F. Secord, architect, Toronto, has moved his office from 17 Queen Street East to 2 College Street and is now associated with Messrs. Geo. N. Molesworth and Gordon M. West, who are on active service. Captain Molesworth is with the 124th and Lieut. West with the 81st battalion.

Mr. E. Laurie, of the E. Laurie Company, Montreal, agents of the DeLaval Steam Turbine Company, is now in England, having joined the Aviation Corps there. Mr. Laurie received a portion of his training in aviation in Canada. The agency of the DeLaval Company will be continued as before by the E. Laurie Company in Montreal.

Mr. L. Keroack has become associated with Mr. J. O. Marchand under the firm name of Marchand and Keroack, architects, 164 St. James Street, Montreal. Mr. Marchand is the surviving member of the old firm of Marchand and Haskill; the latter died about two years ago, and since then the business has been carried on by Mr. Marchand. Mr. Keroack is one of the younger members of the Province of Quebec Association of Architects.

Obituary

Mr. G. D. Walters, chief agricultural engineer for the irrigation branch of the Department of the Interior, Calgary, is dead.

Mr. James Carr, a well-known resident of Woodstock, Ont., died recently, after a few days' illness, at the age of 78. He was president of the Good Roads Association, and an expert in that branch. He was also agent for the immigration department of the local government. He was born in Woodstock, and spent nearly all his life in that town.

Mr. Alexander Ramsay, president of the A. Ramsay & Son Company, paint and varnish makers, died suddenly on January 14 at his residence, Argyle Avenue, Westmount, aged 76. Mr. Ramsay was a native of Glasgow, but was educated in Montreal, and in 1867 acquired the paint and varnish business established by his father. Under his direction the trade increased very largely.

Charles Conrad Schneider, an eminent bridge engineer, and a past president of the American Society of Civil Engineers, died at his home in Philadelphia on January 8. He was 72 years old, and during his professional career had been the recipient of many high honors. He was appointed a member of the Quebec Bridge Commission, which investigated the failure of the old Quebec Bridge in 1907, and of the later commission appointed in 1911 by the Canadian Government to supervise the construction of the new bridge. He was awarded the Rowland prize and the Norman medals by the American Society of Civil Engineers for excellent papers on his design of the Niagara cantilever bridge (1886), on structural design of buildings (1905), and on movable bridges (1908). Mr. Schneider was born in Saxony, Germany, in 1843, and graduated as a mechanical engineer from the Royal School of Technology at Chemnitz in 1864, coming to America in 1867. He designed several long span bridges, among them the Fraser River cantilever bridge for the Canadian Pacific Railway in 1882 and the Niagara cantilever bridge in 1883. He designed, with Mr. F. B. Kunz, the Reversible Falls steel arch bridge at St. John, N.B., and was consulting engineer until its completion in 1915. He was the author of General Specifications for Railroad Bridges (1886), for Highway Bridges (1901), and for Structural Steel Work in Buildings (1905).

The death is announced of Mr. Alexander Graham, superintendent of construction in the chief engineer's branch of the Department of Public Works, Ottawa. At the time of his death he was engaged on Government work at Sturgeon Falls, Ont. The late Mr. Graham was born at Bell's Corners fifty-one years ago, but had resided in Ottawa for the greater part of his life. Previous to his connection with the Government work, he was interested for many years in the manufacture of brick and cement blocks.

Mainly Constructional

East and West—From Coast to Coast

The Premier Granite & Sand Company, Montreal, have registered.

The Western Ontario Clay Workers Association will meet in convention at London, Ont., February 22 and 23.

Mr. D. A. F. Graham, of the engineering staff of the C. N. P. R., has been made resident engineer of the company for the city of Vancouver.

A conference on Road Construction for County Road Superintendents and Engineers will be held at the Parliament Buildings, Toronto, February 8-11, 1916.

For the year 1915 the total value of building permits at St. John, N. B., was $346,275. In 1914 the figures were $515,300.

The Constructors' Association of Quebec held their annual assembly in their rooms at 23 St. John Street, Quebec, on January 17. A large number of members were present.

The Board of Control of the city of Toronto have recommended the acceptance of the offer of Mr. C. S. Townsend for a concrete bridge at Mount Pleasant Road for the sum of $45,000.

At the annual meeting of the Manitoba Architects' Association held in Winnipeg on the 17th inst., Col. J. B. Mitchell was elected president; L. H. Jordan, vice-president, and R. G. Hanford re-elected secretary-treasurer.

Nobert-Dugre-Arsenault, Limitee, is the name of a firm incorporated recently to carry on the business of general contractors and builders and civil engineers at Three Rivers, Que. The capital stock of the company is ten thousand dollars.

The Automatic Sprinkler Company of America, Limited, has been incorporated to carry on business in Montreal, with a capital stock of $10,000. The incorporators include T.

Chase Casgrain, E. M. McDougall, and P. F. Casgrain, all of Montreal.

It is stated that Mr. Charles D. Campbell, city engineer of Galt, Ont., has resigned his position in order to give the Council a free hand in connection with the appointment of an engineer under the new by-law reorganizing the Works Department of the city.

Messrs. A. Lindstrom and Nelson, who for several years have been foremen with the Scott & Hudson Building Company, have formed a partnership under the firm name of Lindstrom & Nelson, and will embark in the building and contracting business at Kenora, Ont.

There is a report that the Ross Rifle Company, now employing over 1,500 men and paying two million dollars in salary annually, may leave Quebec and establish in Lindsay, Ont., if their application for an extension of ten years to their exemption from taxes is not granted.

Building statistics for the year 1915 for St. Boniface, Man., are as follows: January, $13,500; February, $70,000; March, $12,135; April, $19,800; May, $14,425; June, $18,550; July, $138,600; August, $1,400; September, $1,650; October, $400; November, $700; December, $2,600; total, $296,760. The total for 1914 was $803,442.

The fair wage officer of the Montreal Council has asked the co-operation of the Builders' Exchange and the Trades & Labor Council in drawing up a fair wage schedule to be inserted in all civic contracts for the present year. In 1915 the schedule was first drawn up and the comments of the Builders' Exchange then requested.

Builders Sales, Limited, is the name of a firm incorporated with a capital stock of $100,000 and head office at Ottawa. The company will manufacture and deal in iron, steel, metals, rails, machinery and tools, etc. The incorporators are F. W. White, E. P. Nunn, F. D. Hogg, A. T. Lewis, and H. E. Newland, all of Ottawa.

Judgment has been rendered in the Supreme Court by Mr. Justice Maclennan awarding the Nova Scotia Construction Company the sum of $175,332 for work done under various contracts in connection with the power company's hydraulic development at St. Timothy. It is stated by the power company's attorneys that an appeal against this judgment will be entered.

Statistics compiled by Mr. Geo. A. McNamee, Secretary-Treasurer of the Third Annual Canadian and International Good Roads Congress, to be held at Sohmer Park, Montreal, March 6th to 10th inclusive, show that at least $15,000,000 will be under appropriation this year for the construction or improvement of roads throughout Canada. Of this sum, $5,000,000 is mentioned as the share of the province of Quebec.

In recognition of his services to the Exchange and of his action in answering the call to the colors by enlisting with the 111th South Waterloo Battalion, the members of the Builders' Exchange of Galt, Preston and Hespeler, at a recent meeting honored Mr. Nelson West, who resigned his position as secretary. Mr. West was presented with a small purse, and in accepting the gift expressed his thanks. Mr. Frank McAuslan was appointed to the vacancy caused by Mr. West's resignation.

That the Hudson Bay Railway will be completed and in operation in time to carry out next season's crop seems to be the opinion of the engineers in charge of the work of construction, according to a report from The Pas. The cantilever bridge over the Nelson River at Manitou Rapids, is partly finished, and it is said the work will be completed by next May. The steel is expected to be at Kettle Rapids by the first of August, where another cantilever bridge has to be built, but as the work will be done in summer-time three months will be sufficient for the construction. If this programme is followed out the road should be ready for operation by next Christmas at the latest.

The Provincial Government of Alberta contemplate the construction of a railway from Athabaska to Fort Vermilion, a distance of three hundred miles, at a cost of from eight to ten million dollars. The project includes the development of coal mines, a fleet of steamers for Peace and McKenzie Rivers, working up mining by-products, etc. The Hon. A. G. MacKay, M.L.A., of Edmonton, is said to be interested in the scheme. The loan will be met by New York bankers, and as no opposition is anticipated it is stated that work will be started with the opening of spring.

Mr. W. B. Timms of Ottawa, a mining engineer specially commissioned by the Federal Government at the request of the Imperial Government to inquire into and investigate molybdenite deposits in British Columbia, is in Vancouver. Mr. Timms, who is a graduate of Queen's University and of the Kingston School of Mines, states that molybdenite is known to exist in British Columbia in paying quantities in only one, or possibly two, places. Ferro-molybdenum is a product now very much in demand by the British Government and the Governments of all the other belligerents for the manufacture of big gun linings.

A dispute between John Quinlan and Company, Montreal, contractors, who are building the civic library, and stonecutters who are working on the job has been the subject of a report by Mr. Laurendeau, city attorney. The contention of John Quinlan and Company was that marble cutters working on machines were not entitled to as much as workmen who worked by hand, furnishing their own tools. The scale asked was 45 cents an hour, and the company paid 45 cents to hand workers and 40 cents to those working on machines for a 10½-hour day. The company considered that the latter class were overpaid as compared with other workmen. The city attorney expressed the opinion that when contractors do not pay according to the scale of fair wages inserted in all civic contracts the difference can be paid by the city to the workmen out of the deposit which contractors make with the city as a guarantee of good faith when tendering for the contract.

The annual business meeting of the Ontario Motor League was held in the King Edward Hotel, Toronto, on the 18th inst. Mr. W. A. McLean, Chief Highway Engineer for Ontario, spoke of the plans for connecting up districts at present isolated because of bad roads. The retiring president of the League, Mr. W. W. Digby, pointed out that the membership had grown from 4,600 to 5,041 in the last year. Resolutions were passed favoring complete reciprocity in regard to the interchanging of license privileges between Ontario and the United States. It was also strongly recommended that legislation should be passed making the carrying of lights on all vehicles compulsory. The Hon. Finlay Macdiarmid, Minister of Public Works for Ontario, explained the working of the new highways act, and the Hon. Francis M. Hugo, Secretary of State for New York, spoke briefly of the great benefit of good roads to the country in general. Mr. L. B. Howland, of Toronto, was elected president for 1916.

Prof. Adam Shortt, civil service commissioner, addressed the Ottawa branch of the Canadian Society of Civil Engineers at a luncheon held in the Russell Hotel on the 13th inst. Taking for his subject "War and the Engineer," Prof. Shortt dealt with the necessity of technical training among the nations of the future as shown by conditions arising in the present war. The soldier was becoming more and more a minor factor in warfare, the speaker said, for the application of technical principles had made a great change in conditions. The army with the largest number of skilled men, engineers and inventors, would win the wars of the future. The present struggle, said Prof. Shortt, had demonstrated that it was a war between engineers and engineering products on both sides, and the futility of attempting to overrun nations by mere strength of numbers had been demonstrated. The manner in which engineering had affected all walks of life, including farming, was briefly touched upon by Prof. Shortt, who said that no institution had become so highly specialized as western farming.

Mr. Frank D. Lyman has purchased the stock, assets, and goodwill of the railway and supply department of John Millen & Son, Limited, Montreal, and is now carrying on business at 323 St. James Street, Montreal, with a branch at 90 Adelaide Street West, Toronto. Stocks are carried at both the Montreal and Toronto warehouses. As soon as a Dominion charter has been granted to a new company now formed the business will be conducted under the name of Lyman & Lyman, Limited. Mr. Lyman has been manager of the department now acquired by him since it was started some nine years ago by John Millen & Son, Limited. The new firm holds a large number of import English, French, and United States agencies including The National Tube Company, Pittsburg, Pa., Shelby Seamless Steel Tubes; Ellwood Ivins Tube Works, Philadelphia, Pa., Steel, Aluminium and Brass Tubes; The Electric Service Supplies Company, Philadelphia, Pa., Electric Railway Supplies and Equipment; Link-Belt Company, Philadelphia, Pa., Silent Chain Drives; Societe Le Carbone, Paris, France, Carbon Brushes; The Chisholm & Moore Manufacturing Company, Cleveland, Ohio, Chain Hoists and Trolleys; Crouse-Hinds Company, Syracuse, N. Y., and Toronto, Ont., Electric Headlights; Graphite Lubricating Company, Bound Brook, N. J., Trolley Bushings and Graphite Bronze Bearings.

The total value of the field crops of the Dominion last year is estimated at the huge figure of $800,000,000. New high records are established, both as to quantity, quality and market value. The earlier estimates as to the grain yields of the Prairie Provinces have had to be revised upward. Canada's total wheat yield is now estimated at 376,303,600 bushels, by the latest official Government report, or 215,023,600 bushels more than the previous year.

Turbine Equipment Co.

The Turbine Equipment Co., Limited, Toronto, who handle the De Laval equipment in Canada, have recently secured the following contracts: Riordon Pulp & Paper Co. Ltd.—1-75 h.p. motor driven De Laval two-stage centrifugal pump; Dominion Coal Co. Sydney, N.S.—2-75 h.p. direct current motor driven De Laval two-stage centrifugal pumps; Brockville Water & Light Commission, for the new filtration plant—1-4,000,000 gallon De Laval steam turbine connected to a De Laval centrifugal pump through the medium of double helical reduction gears—1-3 500,000 gallon De motor driven pump—1-2,000,000 gallon De Laval motor-driven pump—1-C. H. Wheeler jet condenser, pipe, valves, etc.

Canadian Clay-working Machinery

Prominent brickmakers in attendance at the Canadian National Clay Products Association held in Toronto last week are behind a scheme for the formation of a company to manufacture clay-working machinery in Canada. At present ninety per cent. of the clay-working machinery used in Canada is manufactured in the United States. A duty of 40 per cent. makes this machinery very expensive. It is estimated that this scheme of manufacture, if carried out, will be a financial boon to the brick industry. Repairs could be promptly secured, and at a very reduced cost. The brickmakers are very enthusiastic over the scheme, and developments may be expected at any time.

Road Builders' Association

Satisfactory progress is reported on the plans of the Thirteenth Annual Convention of the American Road Builders' Association and the Seventh National Exhibition of machinery and materials which will be held at Mechanical Hall, Pittsburgh, February 28 to March 3. The programme will include the discussion of such topics as "Railway Tracks on Paved Streets," "Adaptability of Paving Materials," Bituminous Surfaces for State Highways," "Concrete Roads," "Recent Tendencies in Stone Block Pavements, Especially With Respect to Size of Blocks," "Foundations," "Control of Openings in Pavements," "Roads at Low Cost for Moderate Traffic," "Effects of Motor Trucks," "Contractors' Suggestions to Engineers," and "Brick Streets and Roads."

The Engineer and Architecture

Mr. G. R. G. Conway, M.Can.Soc.C.E., consulting engineer, Toronto, and late chief engineer of the British Columbia Electric Railway Company of Vancouver, delivered an address before the Ottawa branch of the Canadian Society of Civil Engineers on Friday evening January 21. Mr. Conway's subject was "The Engineer and Standards of Beauty," in which he urged a freer co-operation between engineers and architects in the design of engineering structures, particularly in great public works such as bridges, railway terminals, dams, aqueducts, power houses, highways, etc. The paper was fully illustrated with lantern slides giving examples of engineering structures where this co-operation had been attempted, and, in some cases, successfully carried out.

Toronto-Hamilton Highway

In crediting the equipment used on the work of construction of the Toronto-Hamilton Highway, described in our issue of January 5, we failed to note that one of the cranes used by the Comission and shown in one of the illustrations was manufactured by the Browning Company of Cleveland, Ohio.

Fine Booklet on Moncton, N. B.

The city of Moncton, N. B., have just issued a very handsome booklet describing the industrial advantages of that city. The Contract Record acknowledges with thanks a copy from Messrs. James Reid & Son, contractors, who are responsible for a large number of the fine buildings shown in this booklet.

The preliminary programme of the Twelfth Annual Convention of the American Concrete Institute has been distributed. The convention will be held February 14 to 17 at the Auditorium Building, Chicago. With the convention will be associated an exhibit known as the Cement Show.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Barrie, Ont.
The by-law previously reported as carried is for the purpose of paying for work already completed on Bradford St.

Hamilton, Ont.
The City Council are considering the construction of a sewer on Mountwood Avenue and alterations to some of those in the west end south of Aberdeen Avenue. Engineer, A. F. Macallum.

The City Council intend to start work by day labor in the spring on extensions to the waterworks system. General Manager of the Utilities Commission, E. V. Buchanan.

Niagara Falls, Ont.
The Board of Works are considering the construction of a quantity of 6-inch watermain.

Ottawa, Ont.
Preliminary grading is being done by day labor preparatory to the construction of the Rideau River Driveway. Plans for the pavement not yet prepared.

Toronto, Ont.
The Board of Control will receive tenders until February 1st for the construction of sewers on Cawthia, Connolly and Gilmour Streets and St. Clair Avenue Square. Plans and specifications at Room 6, City Hall.

CONTRACTS AWARDED

Ottawa, Ont.
The City Council have awarded the contract for supply of a quantity of 60-inch circular sewer blocks to the National Fireproof Supply Company, 78 Crescent Street, Montreal.

Railroads, and Bridges Wharves

Alberta Province
Negotiations are now progressing with reference to the construction of a railroad between Athabaska and Fort Vermillion at an approximate cost of $10,000,000. The project includes the development of mines and a fleet of steamers for the Peace and McKenzie Rivers. Hon. A. B. MacKay, M.P.P., 10619 99th Avenue, Edmonton, is interested in the scheme.

Brokenhead, Man.
The Municipality are considering the construction of a bridge over the Brokenhead River and repairs to several others. Clerk, W. J. Hoban, Beausejour.

Cameron, Man.
Tenders on the construction of a wooden bridge over the Souris River will be received until February 3rd by the Municipal Secretary, T. B. Woodhull, Hartney.

Lachute, Que.
Tenders on the construction of a bridge will be received until noon, February 3rd, by J. A. Rice, Town Clerk. Steel construction, cement abutments. Plans and specifications with the Clerk.

Toronto, Ont.
The estimates prepared by Parks Commissioner C. E. Chambers include a cement bridge over the lagoon at the Island.

CONTRACTS AWARDED

Toronto, Ont.
The Board of Control have let the contract for the construction of the Mount Pleasant Road bridge to C. J. Townsend, 79 Spadina Avenue, at $45,000, subject to the approval of Council. Concrete construction.

Public Buildings, Churches and Schools

Ameliasburg Township, Ont.
The erection of schools is being considered by the Trustees of School Sections Nos. 12 and 13. Secretaries, R. H. Fox, Ameliasburg, and Arklen Blakely, Consecon.

Athol Township, Ont.
The Trustees of School Section No. 1 are considering the erection of a school. Secretary, M. Parks, Woodrows, Ont.

Barber Township, Ont.
The erection of a school in School Section No. 1 is contemplated. Secretary to the Trustees, J. W. Thompson, Leeville, Ont.

Berthier, Que.
The Parish School Board are considering the erection of a school at an approximate cost of $1,000. Secretary, J. A. A. Lavallee, Berthier.

Casgrain Township, Ont.
The Trustees of School Section No. 1 contemplate the building of a school. Secretary, J. O'Donnell, Hearst.

Catherine Township, Ont.
The erection of a school is contemplated by the Trustees of School Section No. 1. Secretary, W. G. Laycock, Krugersdorf.

Charlottetown, P.E.I.
Tenders will be called shortly for seating required by the First Methodist Church. Approximate cost, $5,000. Secretary, E. H. Beer, 131 Richmond Street.

Currie Township, Ont.
It is proposed to build a school in School Section No. 2. Secretary to the Trustees, G. Sexsmith, Matheson.

Darling Township, Ont.
It is proposed to build a school in School Section No. 1. Secretary, James Burns, Marble Bluff P. O., Ont.

Dundas, Ont.
Oborn & Ellis, Architects, have prepared three different designs for a high School, estimated to cost between $4,500 and $8,000. The sites will be inspected by the Board of Education and a recommendation made.

Eastview, Ont.
The erection of a four-roomed addition to the school is being considered by the Public School Board. Secretary J. W. Rostetter, Cummings Bridge P. O.

Finch Township, Ont.
The erection of a school is contemplated by the Trustees of Union Section No. 3, Finch. Estimated cost, $12,000 to $15,000. Secretary, G. S. Casselman, Finch Village.

Fisher and Herrick Townships, Ont.
The erection of a school is being considered. Secretary to the School Section, A. S. Chapman, Batchewan, Ont.

Fullerton and Downie Townships, Ont.
The Trustees of Union School Section No. 1, contemplate the erection of a school at an approximate cost of $4,800 Secretary, G. S. Thompson, St. Marys, R. R. No. 5.

Georgina Township, Ont.
The erection of a school is being considered by the Trustees of School Section No. 14. Estimated cost, $3,500 Secretary, E. G. Corner, Pefferlaw.

Goulburn Township, Ont.
The Trustees of School Section No. 10 are considering the erection of a school. Secretary, F. McCaffrey, Stanley's Corners.

Halowell Township, Ont.
The Trustees of School Sections Nos 6 and 12 are considering the erection of two schools. Secretaries, R. D. Milford, R. R. No. 1, Picton, and T. G Wright, R. R. No. 8, Picton, Ont.

Hamilton, Ont.
The General Hospital Board contemplate the erection of an administration building in connection with the Hospital Chairman, T. H. Pratt.

Iroquois Falls, Ont.
The construction of a school is contemplated. Secretary to the School Board, F. Lyons, Iroquois Falls

London, Ont.
The School Board are considering the erection of a technical school, a public school south of Dundas Street and east of Egerton Street, and additions and alterations to the suburban school at Ealing. Chairman, A. E. Silverwood.

The installation of a passenger elevator at the City Hall is contemplated. City Clerk, S. Baker.

The Board of Education are considering extensive improvements in the ventilation of several schools. Chairman, A. E. Silverwood.

Manvers Township, Ont.
The Trustees of School Section No. 1 are considering the erection of a school at an approximate cost of $3,000. Secretary, A. W. Hesslip, Janetville, R. R. No. 2.

Marlborough Township, Ont.
The erection of a school is being considered by the Trustees of School Section No. 4. Secretary, Henry Taylor, Malakoff.

Pictou, N.S.
The Pictou County Council are considering the erection of a new asylum near to the present one, which is becoming overcrowded. Treasurer, A. McDougall, Pictou.

Prevost Canton, Que.
The erection of a school at an estimated cost of $4,000 is contemplated. Secretary to the School Board, J. Lachance, St. Zenon P. O.

Renfrew, Ont.
The Department of Public Works, Ottawa, are considering the erection of an addition to the Post Office. Secretary, R. C. Desrochers, Ottawa.

Sharpe Township, Ont.
The erection of a school is contemplated by the Trustees of School Section No. 4, Marlborough. Secretary, Otti Stein, Costello.

South Marysburg Township, Ont.
The erection of schools is being considered by the Trustees of School Sections Nos. 13 and 15. Secretaries, J. W. MacAuley, Milford, Ont., and J. E. Murphy, South Bay, Ont.

St. Emile de Suffolk, Que.
The School Board contemplate the erection of a school at an approximate cost of $4,000. Secretary, A. D. Boivin, St. Emile de Suffolk.

Timmins, Ont.
The School Board contemplate the construction of a four-roomed school. Secretary, Adrien Allard, Timmins.

Tiny Township, Ont.
The Trustees of School Section No. 5 are considering the erection of a school, estimated to cost $4,000. Secretary, W. A. Casselman, Wyebridge.

Toronto, Ont.
The general contract for the erection of a temporary postal station has been awarded by the Dominion Government Department of Public Works to William Williamson, 131 Woodbine Avenue. Steel, galvanized iron and brick construction.

The Board of Education will receive tenders until January 28th for sundry work at the schools, including ash hoists, electric wiring, fire door, steam fittings and supply of drawing tables and side arm chairs. Specifications, etc., at office of the Building Superintendent.

Wellington, Ont.
The erection of a school is being considered by the Trustees of School Section No. 14, Hillier Township. Secretary, E. L. Hubbs, Wellington.

West Wawanosh Township, Ont.
Tenders will be called about the middle of February on the erection of a school for the Trustees of School Section No. 4. Plans are now at residence of the Secretary, W. McQuillan, R. R. No. 4, St. Helens P. O. Architect, A. Stuart, Lucknow. Estimated cost, $4,000.

Windsor, Ont.
Sub-tenders on trades required in the erection of an addition to the Collegiate Institute are being received by Schultz Bros. Company, Limited, Brantford, and John McLeod & Company, Limited, 110 Church Street, Toronto.

CONTRACTS AWARDED

Motherwell, Ont.
The School Board have let the following contracts for the school which is to be erected in the spring:—masonry, Brown & Sparks; carpentry, C. Kane; painting, W. Swan; plumbing, P. Warner; all in care of the Secretary, W. W. Rogers. Seating will be purchased later.

Business Buildings and Industrial Plants

Cape Breton, N.S.
The International Nickel Company, 43 Exchange Street, New York City, and Sudbury, Ont., have made arrangements with the Dominion Government for the establishment of a nickel refinery. President, Ambrose Monell.

Deseronto, Ont.
The Canadian Northern Railway Company, Toronto, contemplate the construction of cattle pens. Work will be done by the Company's Bridge & Building Department. Frame construction.

Galt, Ont.
The Canadian Cereal & Flour Mills Company, Limited, propose to add two storeys to their warehouse, and have applied for a permit. Secretary, R. C. Pratt.

Hamilton, Ont.
The Fire Chief, A. B. Ten Eyck, has recommended the erection of a fire hall in the southwestern section of the city.

Montreal, Que.
Work has been started by N. D. Leger, 2516 Chateaubriand Street, on the erection of a store and residence on Church Street. A number of trades will be sublet shortly.

Ottawa, Ont.
New tenders will be called shortly for alterations and additions to stores on Albert Street for J. G. Butterworth, 86 Sparks Street. Architect, W. H. George, Castle Building, Queen Street. Steel and brick construction, concrete foundation, felt and gravel roofing.

Tenders are now being received for alterations and additions to stores at O'Connor and Slater Streets for J. Brouse, 85 MacLaren Street. Architect, W. Herbert George, Castle Building, Queen Street. Brick construction, concrete foundation, felt and gravel roofing.

Port Arthur, Ont.
The Davidson & Smith Elevator Company propose to construct an additional storage with a capacity of 1,000,000 bushels. Particulars from J. R. Smith.

Quebec, Que.
Work will start in the spring on the construction of stock yards, etc., for the Quebec Abattoir Company, Limoilou. Day labor will probably be employed. Architect, A. H. Laberge, Beauport. Estimated cost, $35,000.

Sarnia, Ont.
Lockwood, Green & Company, Boston, are now negotiating with a view to the erection of a factory. Estimated cost, $500,000.

Tavistock, Ont.
The Dominion Railway Board Inspector will recommend the construction of a new station by the Grand Trunk Railway Company, Montreal.

Toronto, Ont.
R. T. Robinson, 131 Glenholme Avenue, has commenced the erection of a pair of stores at 754 St. Clair Avenue. The contract for plumbing has been let to E. F. Rockford, 880a Bloor Street W. Roofing, painting, plastering, wiring and heating not yet awarded.

The Grand Trunk Railway Company have started work on repairs to the roof and top floors of the Union Station under the supervision of Engineer Mitchell, Department of Bridges and Buildings. Approximate cost, $10,000.

Witchall & Son, 156 St. Helens Avenue, are receiving sub-tenders in connection with the power station which is to be erected near Orillia.

Vancouver, B.C.
Tenders will be called about the end of the month for foundation work, piling and concreting in connection with the erection of a station for the Great Northern Railway, 90 Pender Street E. Architect, F. L. Townley, 850 Hastings Street W. Estimated cost of this work is $30,000.

CONTRACTS AWARDED

Hamilton, Ont.
The contract for plumbing required in connection with the warehouse which has been erected for M. Jax, 94 Cannon St. W., has been let to D. Robinson, 315 John Street N.

Montreal, Que.
The contract for electrical work required in connection with the stores and residences which are being built for J. Leclaire, 600 Demontigny Street, has been let to Raoul Chamberland, 825 Delorimier Avenue.

In connection with the factory which has been erected for the Steel Company of Canada, 1272 Notre Dame Street W., the contract for heating and ventilation has been let to the B. F. Sturtevant Company of Canada, New Birks Building, and the plumbing to T. O'Connell, 183 Ottawa Street.

In connection with the premises which are being erected at Bank and Sunnyside Streets for Graham Bros., 205 Laurier Avenue, the contract for heating and plumbing has been awarded to Gervin

& Lillico, 1095 Bank Street, and the electrical work to F. Presby, 138 Irving Ave.

Toronto, Ont.
The contract for masonry and stone work required in connection with the store and residence which is being built by J. P. Lever, 20 Atlas Avenue, has been awarded to the Granite Concrete Block Company, Limited, 1466 Yonge St.

Residences

Ailsa Craig, Ont.
The congregation of the Baptist Church are considering the erection of a parsonage, at an approximate cost of $5,000. Chairman of the Building Committee, S. Gillies.

Albertville, Ont.
William Woollatt, care of R. Wigle, Albertville, Kingsville, Ont., is considering the erection of a residence at an approximate cost of $3,500.

Beverley Township, Ont.
Hayward Cornell, R. R. No. 1, Troy, contemplates the erection of a residence. Brick construction, stone foundation.

Brockville, Ont.
Tenders will be received until February 7th for alterations to the residence of J. A. Mackay, Prescott Road. Architects, Barott, Blackader & Webster, New Birks Building, Montreal.

Hagersville, Ont.
Work will start early in the spring on the erection of two residences for Frank Tyrrel. Brick construction.

William Herod is considering the erection of a residence on King Street. Work may start in the spring.

Lakeside, Que.
The roofing required in connection with the residence in course of erection for C. W. MacLean is being done by day labor.

Montreal, Que.
Work has been started on the erection of four flats on Clark Street for H. Paiement, 1335 Gouin Boulevard. Brick construction, concrete foundation, felt and gravel roofing. Estimated cost, $20,000.

Niagara Falls, Ont.
William Hanover, Ferry Street, has commenced the erection of a residence on McRae Street, and contemplates building another on Armoury Avenue. Brick construction. Estimated cost, $3,000 each.

Ottawa, Ont.
Eugene Patry, 54 Irving Avenue, is about to start work on the erection of a residence, estimated to cost $3,500. Brick veneer construction, stone foundation, felt and gravel roofing.

Quebec, Que.
Work has been started by Leon Marcoux, 67 Napoleon Street, on the erection of a residence, estimated to cost $4,000. Frame and brick construction, stone foundation, felt and gravel roofing.

Ridgeville, Ont.
The erection of a residence is being considered by F. C. Williams. Work may start in the spring. Cement block construction.

CONTRACTS AWARDED

Ottawa, Ont.
The contract for heating and plumbing in connection with the residence which has been built by B. A. Grison, 21 Fentiman Avenue, has been awarded to Gervin & Lillico, 1095 Bank Street.

In connection with the residence which Walter Fryer, 5 Glen Avenue, has built on Roslyn Street, the contract for electrical work has been let to the Dominion Electric Construction Company, 417 Sparks Street.

In connection with the residence which is being built on Fentiman Avenue by F. Nunn, care of Ritchie & Nunn, 165 Sunnyside Avenue, the contract for heating has been let to J. Cameron, 488 Levis Street, the plumbing to J. P. Band, Bank Street, and the electrical work to H. L. Allan, 377 Somerset Street.

In connection with the residence which is being erected on Grove Street by John McCallum, 54 Glen Avenue, the contract for heating has been awarded to the Capital Hardware Company, Bank Street, and the plumbing to H. Knox, Elgin St. Painting by owner. Electrical work not let.

The following contracts have been let in connection with the residence which is being let in connection with the residence which is being built on Marlboro Avenue by Barrett Bros., 260 Catherine Street:—plastering, P. Beaupre, 13 Heney Street; painting, Bower Bros., 48 Aylmer Avenue; heating, John Stewart, Westboro; plumbing, J. T. Blythe, Frank Street.

In connection with the residence which is being erected on Fourth Avenue for A. Davidson, 69 Grosvenor Street, the contract for heating and plumbing has been awarded to Gervin & Lillico, 1093 Bank Street, and the electrical work to the Dominion Electric Construction Company, 477 Sparks Street.

Power Plants, Electricity and Telephones

Ailsa Craig, Ont.
William Hay contemplates the purchase of electrical machinery for operating his mill.

Amherstburg, Ont.
The Town Council are considering extensions to the existing lighting system and will later take up the question of installing a permanent lighting system. Clerk, G. E. Pulford.

Stamford Township, Ont.
The Township Council are considering the purchase of the electric plant of the Ontario Distributing Company and the erection of a sub-station at a total cost of $26,000. A by-law may be submitted to the ratepayers to authorize this expenditure. Estimated cost of sub-station, $3,000. Clerk, C. T. Monroe, Southend P. O.

Wellesley, Ont.
The Town Council will call for tenders within two months for the installation of a distribution plant. Estimated cost, $7,500.

CONTRACTS AWARDED

Montreal, Que.
In connection with the projected addition to the steam generating plant of the Montreal Tramways Company, 78 Craig Street, the contract for boilers has been awarded to Babcock & Wilcox, Limited, College Street, and for a turbo generator to the Canadian General Electric Company, Limited, 162 St. Antoine Street.

Fires

Amherst, N.S.
A business block owned by E. E. Hewson has been damaged by fire to the extent of about $4,000. Loss partially covered by insurance.

Birchcliffe, Ont.
The residence of A. F. Harris has been destroyed by fire. Loss, $2,000

Brandon, Man.
Fire has destroyed a store owned by Doig Rankin & Robertson Loss, $100,000.

Collingwood, Ont.
The store of Honeyford & Vernon has been damaged by fire to the extent of $15,000, including loss on stock. Some insurance is carried.

D'Israeli, Que.
Four residences have been destroyed by fire. Owners, John Gauthier, Severe Blanchard, J. A. Bengle, M. Levesue Loss, $10,000, covered by insurance.

Fairville, N.B.
Glendon H. Allen's drug store, the property of Robert Catherwood, has been destroyed by fire. Loss, $4,000, partially insured.

Fort William, Ont.
Fire has destroyed the music store on Arthur Street owned by J. R. Tucker.

A store at McTavish and McIntyre Streets, owned by Ignace Firlewrez, has been destroyed by fire. Loss, about $2,500, covered by insurance.

Galt, Ont.
Fire has destroyed the wooden grandstand in Dickson Park, owned by the Town Council. Loss, $5,000.

Hamilton, Ont.
The store of Kent Garvin & Company, 10 Catherine Street N., has been destroyed by fire. Loss on building and contents, $10,000.

Harriston, Ont.
The Town Hall has been destroyed by fire. The Town Council will rebuild. Clerk, A. J. Stewart.

Moncton, N.B.
Fire has damaged a building on Main Street owned by W. S. Smith, Main St

Montreal, Que.
The premises of the Canadian Architectural Iron Works Company have been entirely destroyed by fire.

Oil Springs, Ont.
Fire has destroyed the store of W. R. Wiggins. Loss, $5,000.

Fire has totally destroyed a store owned by Mrs. W. S. Duggan

Ottawa, Ont.
The residence of Alexander Abraham, 619 Booth Street, has been destroyed by fire. Loss, $2,500. Owner may rebuild

Quesnel, B.C.
Fire has destroyed the following pre-

Tenders and For Sale Department

Tenders Wanted

Tenders will be received by the Council of the Township of Hullett up to 2 p.m. on **Thursday, the 3rd of February, 1916**, for the erection of a steel bridge over the Walkerburn Creek, five miles north of Londesboro, the said bridge to be 60 ft. long and 16 ft. roadway, with cement floor and to be built on cement abutments. The lowest or any tender not necessarily accepted.

3-4 JAMES CAMPBELL, Clerk.

Tenders Wanted

Sealed tenders for all trades, with the exception of structural steel, in connection with the erection of the New Princess Theatre, Toronto, will be received until 5 p.m., **Saturday, February 12, 1916**, at the office of the undersigned.

Structural steel tenders will close at 5 p.m., Saturday, February 5, 1916.

Tenders to be submitted on forms to be supplied.

Plans and specifications may be seen at the office of Charles J. Read, Rooms 203-4 Confederation Life Building, Toronto, Ont.

C. HOWARD CRANE, Architect,
CHARLES J. READ, Associate Architect.
4-5-6

Separate sealed tenders, addressed to the undersigned, will be received at this office until 4 p.m., on **Tuesday, February 15, 1916**, for the supply of: "Brooms and Brushes," "Chain," "Coal," "Hardware," "Hose," "Oils and Greases," "Packing," "Paint and Paint Oils," "Manilla Rope," "Wire Rope" and "Steam Pipe, Valves and Fittings," for the requirements of the Departmental Dredging Plant in Ontario and Quebec during the fiscal year 1916-1917.

Each tender must be sent in a separate envelope and endorsed: "Tender for Hardware, Ontario and Quebec," "Tender for Chain, Ontario and Quebec," etc., etc., as the case may be.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures. These forms can be obtained at the Department of Public Works, Ottawa.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, for amount stated in form of tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the contract. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, January 21, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—90556. 4-5

AGENTS WANTED

Canadian sales agents wanted by large company manufacturing road making and contractors' machinery. Box 297, Contract Record and Engineering Review, Toronto, Ont. 4-7

For Sale

Large manufacturing company in the United States specializing in concrete machinery wants to sell outright a full set of drawings, patterns, and other information in reference to building and marketing concrete mixers. Good opportunity for Canadian manufacturer. Box 296, Contract Record and Engineering Review, Toronto, Ont. 4-6

Contractor's Plant For Sale

Two Ransom, 10 cubic feet capacity, Concrete Mixers, one equipped with loading skip, complete with steam engine.

One Beatty Hoisting Engine, single drum, double cylinder, 14 h.p., A1 condition.

One American Single Drum Hoisting Engine, single cylinder, 16 h.p.

Ten concrete carts, tools, etc.

Will dispose of at sacrifice price, and make terms of payment to suit purchaser. Apply Mr. Creed, Room 903, Read Building, Montreal. 3-4

WANTED

Two Mobile Switching Type Locomotives on rental, purchase basis, 16 x 24 inch cylinders, 4 or 6 wheels, with 3-inch tires, wheels not more than 44-in. center, sloping tender, capacity 2,500 gallons water and 4 tons coal, fitted with Westinghouse Brakes.

One Standard Gauge Contractors' Dinkey.

One ¾ Yard Revolving Shovel.

Box 298, Contract Record & Engineering Review, Toronto, Ont. 4-4

Concrete Mixers

Large company in Middle States making concrete mixers wants selling agents for Canadian territory. Good working arrangement and substantial assistance will be given to reliable aggressive agents. Box 279, Contract Record, Toronto, Ont. 1-4

Late News Items

Collingwood, Ont.
Plans for alterations to the waterworks system have been submitted to the Town Council by Consulting Engineer Willis Chipman, Mail Building, Toronto. They include the installation of an electric high lift pump and the construction of a water tower and pump well, complete with apparatus. Estimated cost, $19,000.

Cornwall, Ont.
The contract for electrical work required in connection with the warehouse which has been built for Canadian Cotton's Limited, 28 Victoria Street, Montreal, has been let to Goodwin's, Limited, St. Catherine Street West, Montreal.

Grand'Mere, Que.
The Town Council have let the contract for electric equipment to the Canadian General Electric Company, Limited, 162 St. Antoine Street, Montreal.

London, Ont.
Dennis H. Flannigan, 840 Lorne Avenue, intends to proceed with the stockyards scheme which was defeated recently by the Municipality. Plans will be prepared. Estimated cost, $7,000.

Smallman & Ingram Limited, Dundas Street, are considering extensive alterations to their premises. Architects, Watt & Blackwell, Bank of Toronto Building. Approximate cost, $20,000.

Montreal, Que.
Tenders will be received until January 31st for repairs to the grand stand at Blue Bonnets Race Track for the Montreal Jockey Club. Work includes foundations, masonry, concrete and architectural iron. Architect, R. E. Bostrom, 221 McGill Building.

F. Leduc, 314 Melrose Street, has commenced the erection of flats on Decarie Boulevard, estimated to cost $9,000. Subtenders are now being received on roofing, heating, plumbing and electrical work.

In connection with the flats which have been erected by Owen Roberts, 112 Addington Avenue, the contract for painting has been awarded to J. Cyr, 47 Lacasse Street, and the electrical work to the Ellwood Electric Company, 1830 St. Catherine Street E.

Outremont, Que.
The contract for roofing required at the cottage which has been erected on Hartland Avenue for R. J. Cornforth, 1720 Hutchison Street, has been let to Campbell, Gilday Company, Limited, 793 St. Paul Street, and the electrical work to the Electric Repair & Contracting Company, Limited, 317 Craig Street W.

Stanstead, Que.
The general contract for the erection of a registry office and municipal hall for the County Council has been awarded to Loomis, Dakin Limited, St. Gabriel Street, Sherbrooke, Que. Estimated cost, $10,000.

West Garafraxa Township, Ont.
Tenders on the erection of a residence will be received until February 1st by John Paton, R. R. No. 4, Fergus. Brick construction, stone foundation.

Sand should always be tested, according to Sanford E. Thompson in a paper on "Concrete Aggregates" presented before the International Engineering Congress. A table of results of actual tests showing variation in strength of mortars made with different sands compared to standard Ottawa sand is given in proof of this conclusion. The most satisfactory test is the determination of the strength of the mortar made up with the cement and fine aggregate to be used on the work in comparison with identical specimens made in the same proportions with standard sand.

The Aeration of Sewage

It is little more than a year since the treatment of sewage by forced aeration was announced in England. Yet several plants employing this method are already built, or under design by engineers, who feel that the experiments made justify their confidence. There are, however, a great many things yet to be investigated—such as the effect of relatively low temperature in winter on the process; how nitrogen in the sludge can best be built up; how much sludge will be formed under various conditions of operation, and whether a cycle or process of operation employing a series of tanks can be devised in such a manner that all of the easily reducible organics will be removed from both sewage and sludge; how much sludge will be available for the manufacture of fertilizer, and whether all that is of value may not be required for use in the continuous flow plan of sewage treatment to diminish the time of aeration to a minimum. Briefly, the process may be described as a reversal of the filtration method, in that the purifying medium is moved up and down through a tank of sewage, rather than the liquid moved through a bed of stone or gravel, each particle of which is surrounded by a film containing bacterial growths.

This method of sewage treatment has long engaged the attention of sanitarians, but only recently has it been sufficiently developed for adoption in a full-scale plant. One of the first experimental plants was completed and put in operation at Brooklyn on January 1, 1914. The first experiments carried on there were in a specially designed tank—called a tank aerator—built of wood, 12 ft. in diameter and 28 ft. 8 ins. deep, with a capacity of 16,000 gals. Compressed air was supplied by means of a pipe-grid placed at the bottom of the tank on a 7½ in. layer of broken stone passing a 2-in. ring. Over the grid is placed another similar layer of stone. The sewage enters at the top of the tank, through ports at the water-line, and the effluent is taken off by an outlet pipe at the botttom. The tank is equipped with peculiarly designed discs, which are intended to act as colloidors as well as deflectors of the flowing mass of sewage, and to give greater internal surface area within the sewage content for bacterial residence.

The result of a series of experiments proved that it is possible by this means alone, in a continuously flowing tank, without the employment of the activated sludge method, to produce a well-clarified and stable effluent, with a retention of 24 hours. Indications pointed to a possible shorter retention period, but the cost compared with that of the percolating filter seemed so unfavorable that at the close of the year 1914 the tank was changed over to an activated sludge tank. In order to proceed with activated sludge experiments it was only necessary to modify the aerator tank by introducing an outlet at about two-thirds of the depth of the tank, e.g., so that at each drawing 6,000 gals. of the settled sludge could be retained, discharging 10,000 gals. of clarified effluent.

Do not fail to read the article by Cosmo Hamilton on page 113 of this issue. "England's Malady" and the evils of the party system are portrayed in telling characters.

The importance of an experimental unit operating on the continuous flow plan was appreciated, and during the summer of 1915 three variations in designs for such a unit were tried out. All these designs were based on different modifications of the familiar settling or flowing-through chamber of an Imhoff tank, and gave a very good effluent. The work done so far on activated sludge does not justify positive conclusions, but offers considerable promise.

That Montreal Aqueduct

In the course of his address as president of the Montreal Board of Trade, on Jan. 26, Mr. G. F. Benson referred in the following terms to the controversy over the enlarged aqueduct: "I would particularly call your attention to the matter of the opposition of the Canadian Society of Civil Engineers to the present aqueduct scheme and the letter sent by our council to the Board of Commissioners. This is a question that

I think needs the very careful attention of your new council and of the members of this board. The statement is made that as a scheme for the development of power by the city, the enlargement of the aqueduct, as now proposed, is not an economic commercial proposition. It would seem to be leading to a cost of development that will greatly exceed that of any modern hydro-electric development, and the figures would indicate that it will result in a cost per horse power to the city higher even than the cost of development by steam power, and considerably higher than the present contract price that the city is now paying for electric power. The question also arises as to whether it is in any case wise to make the city dependent upon one source of hydro-electric power, in view of the well known troubles from frazil and back-water during the winter season, referred to in the letter addressed by your council to the Board of Commissioners."

Quebec Road Expenditures

Some particulars regarding expenditure on Quebec roads were given by the Hon. W. G. Mitchell, the Provincial Treasurer, during his speech on the Budget. The Government, he stated, was authorized to contract loans to the extent of $15,000,000, the proceeds to be expended in grants to municipalities to aid them in construction of roads under the provisions of the Good Roads Act and in the construction of Government roads, in accordance with the act. He also submitted the following statement:

Payments to municipalities to date.....	$ 8,162,574.43
Payments on Government roads to date	4,137,725.63
	$12,300,300.06
Net proceeds of loans	5,850,805.32
Excess of payments over proceeds of loans	6,449,494.74
Amount allocated to municipalities to date	$ 8,768,787.37
Amount paid on same	8,162,574.43
Balance to be paid	$ 606,212.94

A comparison between this statement and the similar one to 31st December, 1914, showed that during the calendar year 1915 there was paid to the municipalities the sum of $1,931,915.47, and expended on Government roads the sum of $1,957,956.35. It would also be seen that the amount that can hereafter be spent under the Good Roads Act is the difference between the $12,300,300.06 already spent and the amount of the proceeds of permanent loans for $15,000,000.00, which difference will probably not exceed $2,400,000.00.

Our Returned Soldiers

As the first result of the report recently issued by the Hospital Commission, a Soldiers' Aid Commission for Ontario has been established. The care of a soldier who has returned to Canada mutilated or weakened as a result of active service is the prime duty of Canadians. Each soldier is interviewed at Quebec on his return by a representative of the Canadian Patriotic Fund, and a confidential report is sent to the Patriotic Committee of the town to which the soldier is going. This serves the two-fold purpose of protecting the Fund against the greedy or unscrupulous and of giving the local committee information that is helpful in finding employment for the deserving. The Fund also presents a small badge bearing the words "For service at the front" to the deserving soldiers. Men wearing this badge are the worthiest citizens we can acknowledge.

The work of the Canadian Patriotic Fund is limited by Act of Parliament—no person in receipt of a gratuity or pension or allowance paid by His Majesty can receive assistance from the Fund. Because the pensions and gratuities are oft-times admittedly inadequate it has been found necessary to establish a Hospital Commission and Disablement Fund—the Soldiers' Aid Commission of Ontario is the first step in this direction. The latter has announced its intention of mobilizing manufacturers of Ontario, and we do not doubt that the process will be facilitated by the manufacturers themselves. Others also will be asked to lend their aid in discharging a great national duty, and there is every prospect that in Canada at least the traditional tragedy of the returned soldier will have no place.

1916 Officers Can. Soc. Civil Engineers

The complete list of new officers of the Society for the coming year is as follows: President, G. H. Duggan, vice-president and general manager, Dominion Bridge Company, Montreal; Vice-president, T. H. White, chief engineer, C. N. R., Vancouver; Councillors, J. R. W. Ambrose, chief engineer, Toronto Terminals Railway Company, Toronto; H. Donkin, deputy minister, Department of Works and Mines, Halifax; A. E. Doucet, Quebec; W. J. Francis, consulting engineer, Montreal; E. D. Lafleur, chief engineer, Department of Public Works of Canada, Ottawa; D. O. Lewis, district engineer, C. N. R., Victoria; D. A. Ross, consulting engineer, Winnipeg; H. R. Safford, chief engineer, G. T. R., Montreal.

Street Flooding Prevented by Wide Storm-Sewer Intakes

THE problem of handling large volumes of storm water in street gutters without flooding the crossing for pedestrians has been solved in Pasadena, Cal., by the use of long sewer intakes located in the curb adjacent to the street intersections. The intakes are made 30 ft. long, with a 9-in. opening. The sidewalk slab over the intake is of reinforced concrete, 3 ins. thick and supported at the curb line on two steel struts.

The normal flow line of the gutter is lowered 3 ins. and at the end of the intake away from the street intersection this difference in elevation is taken up in a length of 6 feet. At the crossing end, on the other hand, the gutter level is raised to within 2 ins. of the sidewalk level at the point where pedestrians cross. This affords a smooth intersection and a "high and dry" crossing, even in times of heavy storms.

The intakes were designed by R. V. Orbison, city engineer of Pasadena.—Engineering Record.

The latest revised Government report gives 376,303,600 bushels as the total yield of Canadian wheat in 1915. The average yield for all wheat (fall and spring) is 28.96 bushels per acre. The value of all field crops is placed roughly at eight hundred million dollars.

Erection Progress on Quebec Bridge

North anchor and cantilever arms completed — South anchor arm out to and including main post Work to be completed during 1916

By H. P. Borden*

WHEN work on the Quebec Bridge closed down a year ago, the north anchor arm was completed out to the main pier with the exception of two panels of the upper web members and top chord. On the south side no steel at all had been erected between the main and anchor piers.

About the middle of April a start was again made on the erection of the steel on the north shore, and on May 3rd the erection of the main posts was begun. These posts rest on the main shoes over the main pier and are the largest single members in the bridge, being 310 ft. high, centre to centre of pins, and approximately 10 feet square. As the four posts required for the bridge weigh approximately 6,000 tons, costing in the neighborhood of one million dollars, or considerably more than the entire cost of many important bridges, some idea of the magnitude of these members may be obtained. Each of these members is composed of four separate columns latticed together in four directions, terminated by a tapered solid section at both top and bottom. In order to facilitate shipment and handling, each of these members was shipped in twenty-six separate sections and spliced together in the field. It was expected that serious difficulty might be encountered in the erection of these sections as they had to be put in place with splice plates attached to the ends and lowered with extreme precision to allow the webs and flanges of the adjoining section to be entered between the various plates and angles forming the splice. The efficiency of the electrically controlled hoists on the erection traveler, however, was such that this work was carried out with remarkable rapidity, both posts on the north side being erected and sufficiently riveted to allow the traveler to be moved ahead within one month from the time a start was made. Sufficient riveting was done on these members to take care of all erection stresses before any further steel was erected or the traveler moved ahead. This riveting was considered highly advisable rather than filling the holes with bolts and drift pins and riveting later as the work progressed, as it was found from past experience that once a strain was applied to a drifted joint it was absolutely impossible to remove these drifts except by drilling. The cramped space in the interior of these members also made riveting somewhat difficult, but with the use of specially designed jam riveters, which could work in a space down to 14 inches, very satisfactory work was obtained. While in some cases the heads of inside rivets were not perfect, yet, in all cases, tight rivets were obtained.

When the erection of the main post had proceeded to the desired stage, the traveler was moved ahead and the erection of the first panel of the cantilever arm was started. As the bottom chords have a field splice between main panel points, it was necessary to devise some support for these members for riveting this splice before it could be connected to the main panel point. This was accomplished by means of a "flying bridge" or heavy steel platform extending for one full panel length and for the width of the bridge. On this "flying bridge," which was supported by links to the structure above, the bottom chords were assembled and jacked up into their proper alignment, and the centre splices fully riveted up. As each panel was completed the "flying bridge" was moved ahead to the next panel. This work went ahead very rapidly, as all field splices and connections had previously been reamed out in place at the shop, thus avoiding any shop errors or the necessity of making any alterations or changes in the field. As each panel was erected, accurate measurements were taken to see that the alignment was correct. Owing to the extreme accuracy with which this work was manufactured and inspected in the shop, no difficulty of this nature was encountered, the alignment of both the anchor and can-

* Assistant to Chief Engineer—Quebec Bridge.

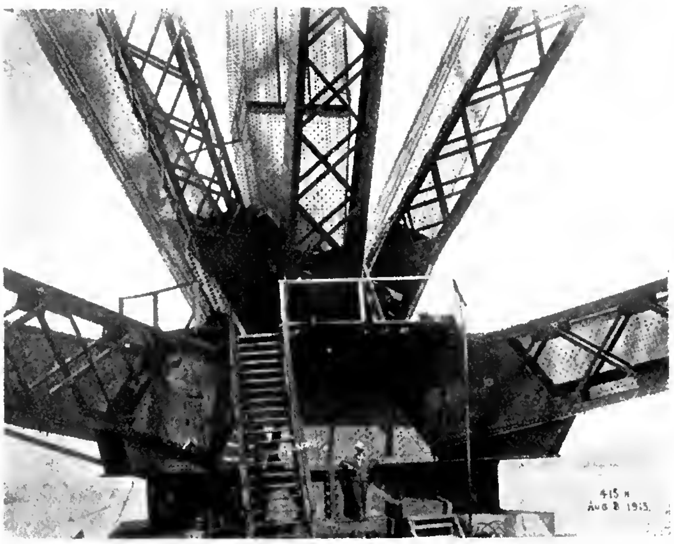

Fig. 2.—Intersection of ten members at the main shoe—Concentrated load on shoe about 55,000,000 lbs.

tilever arms throughout their entire length being absolutely correct.

Members on both sides of the bridge were erected simultaneously by the traveling cranes and stiff-leg booms, and as the traveler moved ahead the sway bracing was put in position by the rear booms. Practically all splices in web members were riveted up complete before moving ahead, or at least sufficiently riveted to carry the full erection stress. Remarkably good records were made in riveting, the percentage of rivets to be cut out being very low. In one case over 4,000 rivets were driven in the splices of the bottom chords, and only one loose rivet was found by the inspectors. This extraordinary record was due, naturally, to the experienced riveters employed on the work, but also to the fact that in reaming out the splices in the shop from 25 to 50 per cent. of bolts were used in bolting up the splice material, thus preventing drillings getting in between the web plates of the member. When the splice was taken apart, care was taken to clean out all drillings that might be found to exist between any parts of the splice material.

By the middle of November the cantilever arm was completely erected, being quite up to the progress laid out by the Bridge Company at the beginning of the season. The work of the traveler having been completed on this side of the river, it is now being taken down and will be re-erected at the site where the suspended span will be erected next year. On the south shore the erection of the falsework to support the anchor arm was started about the middle of April, this falsework being taken from the north shore where it

Fig. 3.—Panel point of bottom chord showing unusual dimensions of members—pneumatic bucker-up, hammer and rivet cutter at work.

had been used to support the north anchor arm. The erection of the anchor arm started on July 7th, and, owing to the experience gained on the north side, was erected much more rapidly, a gain of over six weeks being made in the completion of this work. By the middle of November the entire anchor arm had been erected, including the main posts, with the exception of a certain amount of riveting, which will be completed next year.

During the past season about 30,000 tons of steel

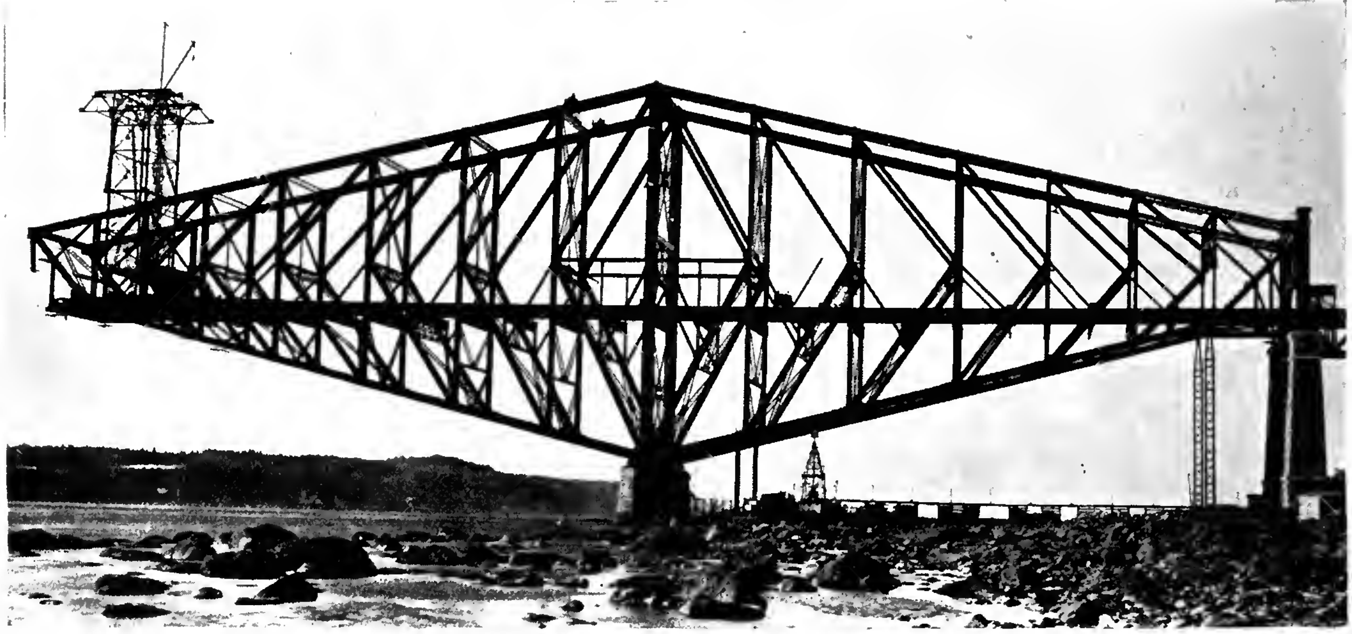

Fig. 4.—Completed north anchor and cantilever arm—Traveller being taken down to be used in the erection of the suspendspan.

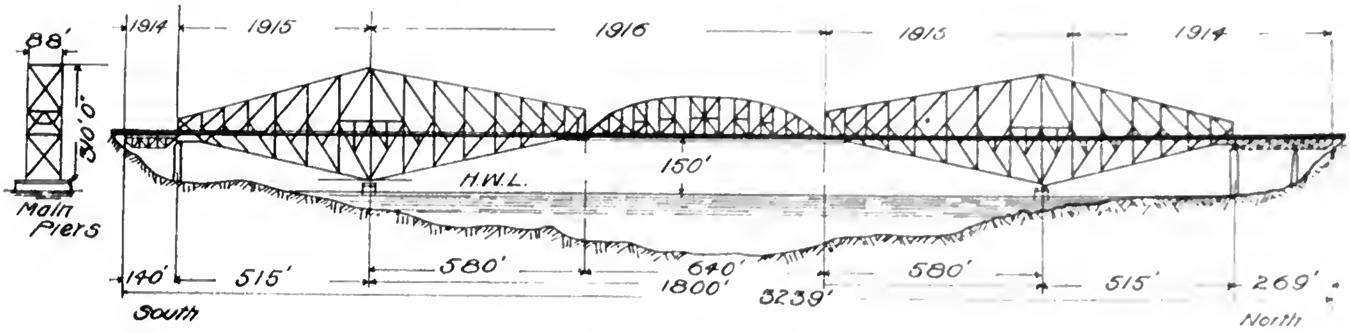

Fig. 5.—Quebec Bridge Progress—shows work done in 1914, 1915 and program for 1916.

was erected. In all about 45,000 tons has been erected out of the 65,000 tons, the estimated total weight of the bridge. The record day's tonnage in 1915 was 670 tons for the south shore traveler, although there were several days in which over 600 tons was erected by this traveler. An average of 350 tons per day was made in the erection of the south main post.

Next season the south cantilever arm will be erected, and it is expected that this work will be finished early in September. The suspended span will also be erected at Sillery Cove, a point some three miles below the bridge site. When completed it will be floated to the site on six pontoons 160 ft. long and 32 ft. wide, each having a working draft of 8 feet. This span, which is 640 ft. long, 110 ft. high at the centre, 88 ft. wide, and weighing about 5,000 tons, will then be attached to long hangers from the ends of the cantilever arms and jacked into place by means of heavy jacks placed on the erection girders at each corner of the cantilever arm. This operation should not take over twenty-four hours if everything works smoothly. By the end of 1915 practically all the steelwork of this bridge should be in place, and it will be possible for working trains to cross the river at this point.

The work is under the supervision of the Board of Engineers, Quebec Bridge, composed of C. N. Monsarrat (Chairman and Chief Engineer) and Ralph Modjeski; (Mr. C. C. Schneider, late member, deceased).

The contract is being carried out by the St. Lawrence Bridge Company, Limited, of which Geo. F. Porter is Engineer of Construction, W. B. Fortune, Superintendent, and S. P. Mitchell, Consulting Engineer of Erection.

The Aeration or Activation of Sewage

New method of sewage treatment sufficiently developed for adoption in full-sized plants—Experimental work at Brooklyn, N.Y., increases confidence in this system.

By G. T. Hammond*

The treatment of sewage by forced aeration, in the presence of activated sludge, is one of the most interesting developments in sanitary disposal methods of recent years. It is but little more than a year since the process was announced in England. Very extensive and careful study has already been given the subject, and numerous papers have appeared concerning it. At the present time, several full-size plants employing this method are building or under design by engineers who feel that what has already been learned about it experimentally justifies their confidence. There are, however, a great many things about it that are unknown, and all admit that much remains to be investigated, either in testing stations at a relatively small expense, or in full-size plants at possibly a larger cost, in order that we may obtain a satisfactory understanding of the many problems that have already presented themselves as to the nature of the phenomena and underlying principles of the method, and as to the essential features of the design of plants and apparatus for its employment.

Some of the problems that are engaging the attention of investigators are the effect of relatively low temperature in winter on the process; how the nitrogen in the sludge can best be built up; how much sludge will be formed under various conditions of operation, and whether a cycle or process of operation employing a series of tanks can be devised in such manner that all of the easily reducible organics will be removed from both sewage and sludge; how much sludge will be available for the manufacture of fertilizer, and whether all that is of value may not be required for use in the continuous flow plan of sewage treatment to diminish the time of aeration to a minimum.

Point of Equilibrium

There is probably a condition of equilibrium to be secured in the treatment under which just about so much sludge will be used by the process to obtain a required result, and just about such a surplus will have to be disposed of. How to adjust the method to the varying strength and quantity of the sewage as it flows to the plant, and the effect of varying strength of sewage on the expense of the treatment, also requires much study.

The efficiency of the method in regular service under the ordinary operation conditions that prevail in all American cities, its cost and economy, and its reliability as compared with other methods of sewage treatment now well known and giving good and cheap service, cannot but engage the careful study of conservative men, whose object usually is to provide the most economical method of treatment which shall offer the greatest promise of efficiency and reliability under existing requirements and circumstances.

Much remains to be learned of the new method

* Presented before section D of the American Association for the Advancement of Science at the Columbus Meeting December 29th, 1915.

along these lines; and while to the scientist investigating it in the experiment plant it seems so promising, a word of caution should be given to the engineer charged at present with designing a sewage treatment plant. Judgment should remain suspended until more definite information is available on the points above mentioned.

Fuller has characterized the process as in a sense a reversal of the filtration method, in that the purifying medium is moved up and down through a tank of sewage, rather than the liquid moved through a bed of stone, each particle of which is surrounded with films containing bacterial growths and their products, all of suitable physical and biological character.

Forced Aeration Process

Wilkinson of Manchester, England, without going into the details of sludge formation, gives about the most concise yet adequate picture, from the engineer's standpoint, of the process, "stripping the theory of all scientific verbiage and putting it in its naked simplicity." We quote, as follows:—

"First of all, in modern plants sewage is usually treated in a percolating filter, by spreading it evenly over the surface, and allowing it to pass through the material to the main under-drainage system. The liquid, in passing through the filter, flows over the surface of the medium, and the more vesicular the character of the latter the better. On starting up a new filter, the sewage shows but little change after passing through, but as time goes on, a growth shows itself in the body of the filter on what may be termed the stationary frame-work, and colonies of bacteria accumulate there, which attack the sewage and effect purification or oxidization of the organic matter.

"These bacteria, being mainly aerobic, an ample supply of air is necessary in order that they may thrive; hence the necessity for adequate ventilation of the under-drainage. That, in brief, is the theory of this, as it appears to an engineer. Let us take a given volume of the stationary frame-work from a ripe filter and carefully remove the coating or growth throughout the material. We shall then have a certain volume of what may be termed sludge, rich in aerobic bacteria, which may be referred to as the activated sludge of this particular process.

Sludge Circulated

"In the new process the active sludge is circulated throughout the sewage in the presence of air, as against the present-day practice of passing sewage in thin films over active sludge retained on a stationary frame-work, as in the case of percolators, for example.

"The real problem, then, is as follows: To ascertain the most economical method of applying air to sewage, with maintenance of complete circulation of the activated sludge without any formation of dead banks of material.

"The problem may now be said to resolve itself into one of reproducing in a tank the changes which take place in a percolating filter. We have our tank, which represents the walls and floor of the filter. We have our colonies of bacteria and the air necessary to support their life, and all we require to do is to provide means for supporting an even distribution of this life throughout the body of the tank, other than by allowing the bacteria to adhere to a stationary framework, such as stone, slate, or clinker material. Compressed air will both insure sufficient agitation and effect the desired results as regards preserving uniform contact and even distribution in the liquid. But at what cost?"

A successful method of sewage treatment by forced aeration has long been an object sought by sanitarians. Observation of the phenomena of the purification which takes place in flowing streams and in foul water in the presence of abundant air, indicated that an intensive method of supplying the oxygen demands and of cultivating bacteria for the purpose of securing a more rapid nitrification, should be possible. But Dibdin tried forced aeration in 1884 and failed with it. In 1890, Dr. Brown and Prof. Leeds of this country, after experimenting, concluded that the oxidation of organic matters in sewage is not facilitated, to any appreciable extent, by forced aeration. In 1894, Col. George E. Waring, Jr., employed forced aeration in a filter with some good effect. After this, nothing of interest is recorded until the matter was taken up in Brooklyn, N.Y., in 1910-11; by Col. William M. Black, U.S.A., and Prof. Earle B. Phelps, who found it possible, by methods designed by them, to reduce the oxygen demand of the sewage one-half to two-thirds, under varying conditions, by applying about two volumes of air per volume of sewage, in a retention period of three hours, although the apparatus was crude and the conditions rather unfavorable. At about the time that the report of these experiments was published, or soon afterwards, the Massachusetts State Board of Health, at the Lawrence experiment station, began experimenting along the same lines, although on a smaller scale in the size of units employed; and in 1913 introduced layers of slate in their aerating tank, by which they secured a very high removal of suspended and coloidal matters and greatly reduced putrescibility. During this work in 1912 at Lawrence, some experiments were made in aerating sewage in bottles, without any contained medium for surface growths other than the inside of the bottle itself. These were seen by Dr. Gilbert Fowler of Manchester, during his American visit of that year, and interested him so much that on his return home he utilized the suggestions and extended the investigation, and the Activated Sludge process resulted.

While the results obtained in Brooklyn previous to 1912 offered much promise, it was not considered that the method was sufficiently developed for adoption in a full scale plant for sewage treatment, and the authorization of funds for installing a sewage experiment plant in Brooklyn, at the very location where Messrs. Black and Phelps have done their work, gave the opportunity in 1913 to include apparatus specially designed to carry their work to a conclusion. The experiment plant was completed and put in service on January 1, 1914, since which time sewage-aeration experiments have been carried on, except in extremely cold weather.

Experimental Plant

The original apparatus did not include special provision for activated sludge experiments, as this method was not announced until the fall of 1914, when this plant had already been in operation nearly a year. The sewage aeration work, however, was provided for, and but slight change in it was necessary to adapt it to the new method in the spring of 1915.

The first series of experiments in sewage aeration were carried on in a tank of special plan, denominated the Tank Aerator. This was designed with the intention of giving a considerable interval surface area for the adherence of bacterial growths, as suggested by Prof. Phelps, and at the same time effecting an even and complete application of the air forced into the tank to the sewage contents thereof.

The result of the series proved beyond question that it is possible by this means alone, in a continuously flowing tank, without the employment of the activated sludge method, to produce a well clarified and stable effluent with the application of 18 volumes of air per volume of sewage, with a retention period of 24 hours. There were indications that this period of retention could be materially shortened, but the cost of the process in comparison with that of the percolating filter, seemed so unfavorable that, after the close of 1914, the tank was changed over to an activated sludge tank.

Tank Aerator

The Tank Aerator is built of wood, 12 feet in diameter and 28 ft. 8 ins. deep. The effective sewage capacity is 16,000 gallons. The compressed air is supplied by means of a pipe-grid, placed at the bottom of the tank, formed of 1½ in. pipe placed at right angles, forming a cross, connected in the center, the arms of the cross being connected with five quarter-circles of ¾ in. pipe, forming concentric rings, each being perforated with 1-16 in. holes at 6 in. intervals. The air enters through the 1½ in. cross pipes and is thence distributed to the rings.

This entire grid is placed on a bed 7½ in. thick, of broken stone passing a 2 in. ring. A layer of broken stone, of the same size and thickness as bed, is placed over the grid. The grid has a connection with the city's water service for use in cleaning it out under pressure.

This method of air distribution has proved very satisfactory, practically no clogging having occurred in two years of service, and the average distribution of air has been very good.

The sewage enters at the top of the tank through eight ports at the water line, each supplied from a pipe which encircles the tank, and, as originally built, the effluent is taken off by four outlets into a common outlet pipe at the bottom.

This tank is equipped with a peculiar design of discs, which are intended to act as colloidors as well as deflectors of the flowing mass of sewage, and to give greater internal surface area within the sewage content for bacterial residence.

There are nine of these discs, all supported by means of a vertical 4 in. pipe placed in the center of the tank. In form, these discs are not unlike wheels. The supporting pipe passes through their hubs. The surface of each is formed of slats about 4 in. wide, spaced one inch apart, with surfaces set 45 degrees with the vertical. The angular surface of the slats towards the center is alternated in direction in each succeeding disc.

Each disc is placed horizontally and occupies the entire cross-section of tank, which is thus divided into a number of compartments, through which the vertical currents of sewage are regulated and streaming prevented, either of sewage passing downward or air passing upward.

Continuous Flow Experiments

The first continuous flow experiments in this tank were not considered at the time as very encouraging. An air supply 0.75 volume per volume of sewage, with 2 hrs. retention, being insufficient to produce any marked improvement over the crude sewage, except a slight dimination in oxygen demand, and some clarification; but our expectations were too high. Continuous flow experiments were therefore suspended for a time and, with the object of ripening the interior surfaces of the tank, the latter was filled with sewage, and beginning on the fill and draw plan, May 19, 1914, air was passed through the sewage for long periods of time, until complete clarification occurred. The contents on settling now showed a high degree of stability. Some of the phenomena of activated sludge were observed, but the desirability of saving the latter was not recognized.

On June 14th, the continuous flow was again employed, with a retention period of 5 hrs., and the application of 3.25 volumes of air per volume of sewage. This failing to give a satisfactory result, the retention period was increased on July 10, to 24 hrs., 18 volumes of air per volume of sewage being used, with marked result. The effluent, after 3 hrs. retention in a secondary settling tank, showed a quality comparable favorably with the settled effluent from a percolating filter. This experiment was carried on until October 1, 1914, when the air was reduced to one-half, or nine volumes per volume of sewage treated, the continuous flow plan being maintained, and the retention period being 24 hours. With 18 volumes of air per volume of sewage from July to October, the settling tank effluent kept improving, the relative stability average being 84 per cent. stable. After the air was reduced to 9 volumes per volume of sewage, the relative stability of the settled effluent fell to 59 per cent.

Contact Aerator

Some interesting results were obtained from an aerated contact filter, on contact aerator, during this same period. This was a small unit operated on the fill and draw plan, suggested by a visit to the Lawrence experiment station early in the spring of 1914.

A tank was seen at Lawrence about 3 ft. by 4 ft. in plan and 2 ft. deep, in which slabs of thin slate were suspended vertically about one inch apart, in which the sewage was treated by compressed air, a circulation of the sewage being secured between the slabs by an ingenious arrangement of the air inlet. The results achieved seemed remarkably good and seemed to us to be largely due to the extensive area that the slates afforded for bacterial residence and for the absorption of coloids. Our thought was that as good if not better result might be obtained in an aerated contact filter bed which would be less costly to instal on a large scale. To make a preliminary experimental test, a small unit was devised, which was filled with broken stone, passing a 2 inch and rejected by a 1 inch ring. The stone bed was 30 inches in depth. The voids afforded a capacity of 20 gallons, compressed air was applied at the bottom. The sewage entered at the top and was discharged at the bottom.

Experiments with this unit extended from May 6th to July 6th, 1914. The average results were as follows:

	Hours Aeration.			
(Sewage 20 gals. at each filling.)	0	2	5	24
Air 0.17 cu. ft. per minute				
Dissolved Oxygen	1.9	1.4	2.5	2.2
Relative stability	2	4	44	79
Dissolved Oxygen demand	252	134	80	68
Air, 0.35 Cu. ft. per minute				
Dissolved Oxygen	2.5	3.7	5.0	7.2

Relative stability	3	13	75	92
Dissolved Oxygen demand	248	92	68	64
Air, 0.64 cu. ft. per minute				
Dissolved Oxygen	1.1	4.9	6.4	6.8
Relative stability	2	62	100	100
Dissolved Oxygen demand	246	62	50	33

During the work of 1914, we did not recognize the activated sludge principle, and it was not until the late fall, when we learned of the work of Dr. Fowler and others, that we began to take it into account and think that probably it had played a considerable part in our aeration results, especially in the work of the contact aerator. By this time the season was so far advanced that we put off work along the new lines suggested until the spring of 1915.

Aerator Tank Modified

In order to proceed with activated sludge experiments, it was only necessary to modify our aerator tank by introducing an outlet at two-thirds of the depth of the tank, so that at each drawing we could retain 6,000 gallons of the settled sludge, discharging 10,000 gallons of clarified effluent.

The operation of this tank as an activated sludge tank began in the middle of March, 1915. Several weeks were required to accumulate a working quantity of the active sludge. The tank was operated on the fill and draw plan. By May 1st, the results with 24 hours aeration showed excellently.

Regular operation was commenced June 1st, on the following cycle:

8 a.m.—Shut off air from tank; allow activated sewage to settle one hour.

9 a.m.—Commence drawing of effluent, taking off 10,000 gallons.

10:30 a.m.—Drawing completed; air turned on; crude sewage valve opened.

12 m.—Tank filled, crude sewage valve closed; air continued on until 8 a.m. of following day.

This cycle was continued from the beginning until the recent shutting down of the tank to make changes in the plant for extending the experiments along new lines.

One of the objects in view was to obtain a considerable range in the effect of time and quantity of air, and the cost. Another was the desirability of having on hand a reservoir of activated sludge to draw from other experiments, especially for the continuous flow tank to be mentioned later on.

The results of an average month's operation in the summer are exhibited below:—

Hours Aeration After Refilling Tank

Refill—	0	2	5	20
Volumes of air per vol. of sewage	1.17	3.50	7.00	24.55
Dissolved Oxygen p.p.m.	0	0.1	0.4	2.5
Relative Stability per cent.	15	38	62	100
Oxygen demand, p.p.m.	56	42	..	8
Suspended solids	35	24	20	14
Nitrogen as Nitrites	0.08	0.11	0.49	1.5
Nitrogen as Nitrates	0.1	0.6	1.2	7.3

The sewage averaged—Dissolved Oxygen P.P.M. 1.0; Relative Stability, 3 per cent.; Oxygen Demand (biologic) P.P.M. 200; Nitrogen as Nitrites and Nitrates, a trace only.

The importance of an experimental unit operating on the continuous flow plan was appreciated, and during the summer three variations in designs for such a unit were tried out, the purpose being for experimental uses rather than to devise a tank for use in a large plant; for it was apparent from the first that the method would probably require a series of tanks for actual sewage disposal work on a full scale; but it was desired to study the phenomena of the continuous flow without interfering with the aerator tank and without disturbing other experimntal work. A tank holding about 1,000 gallons, located directly at the side of the aerator tank, was available for this purpose, and result rather tends to indicate that a continuous flow operation can be secured from a single tank if this should be found necessary.

The small tank in question was, in the clear, 54 inches in diameter and 8 feet deep from the water line. The bottom was of hopper shape. The air was supplied by means of five carborundum discs, all carefully placed at equal level. The top of the tank was successively provided with three different designs of clear effluent chambers for quieting the flow passing out and cutting it off from the air agitation in the body of the tank itself, so that the activated sludge could settle out and fall back into the tank, permitting the quiescent clear effluent to pass off continuously.

All of these designs were based on different modifications of the familiar settling, or "flowing through" chamber of an Imhoff tank, and gave a very good effluent.

The clear effluent chamber in each modification was of about one-tenth the capacity of the tank, giving about one hour's retention when run as below described.

Tank Charge

This tank was charged directly from the large tank with fully ripe activated sludge on July 14th, and crude sewage was admitted at the rate of one-tenth the tank capacity per hour. Air was supplied at the rate of 0.7 cu. ft. per minute. A well clarified effluent was secured, the oxygen demand averaging 27 P.P.M., which would be good enough for our local water ways, especially as the effluent is practically free from suspended settleable solids.

On August 12th, the operation was changed to a retention period of 8 hrs. and 45 mins. passage through the aeration chamber, and 45 mins. sedimentation in the clear effluent chamber. For the first week the result was very gratifying. The effluent was highly clarified, and its demand for oxygen was low, but there was almost a complete absence of dissolved oxygen and nitrates, which rendered the stability low, though the separated effluent continued good.

The tank was then emptied and refilled with a fresh charge of thoroughly activated sludge from the large tank, and the retention reduced to 4½ hrs. aeration and 23 mins. sedimentation. This gave a fair effluent and good clarification; but the result soon became imperfect again, indicating that while thoroughly activated sludge will settle very quickly, it takes a longer time if the activation is imperfect, on account of too short a retention period in the aerating tank.

Preliminary contracts have been awarded in connection with the power plant extensions of the Montreal Tramways Company. It is announced that the contract for boilers has been let to Babcock & Wilcox, Limited, and for a turbo generator to the Canadian General Electric Company.

New Curry Block, Winnipeg, Man.

Reinforced concrete store and office building—To be ultimately ten storeys high—Sets a time record in building Cost to date $250,000

The new Curry Building recently erected at the corner of Portage Avenue, Notre Dame Avenue and Garry Street, Winnipeg, at a cost of $250,000 set a record for this size of reinforced concrete building in Western Canada, being built, complete for occupation, in five months. The building is 266 feet by 130 feet, and, including the basement, is three storeys high. It is built of reinforced concrete, with an exterior finish of terra-cotta backed by plain brick.

The main entrance on Portage Avenue is finished in white marble, with a large revolving door of mahogany; the side entrances and corridors are also white marble, with the interior finish of quarter-cut oak on the ground floor, and mahogany on the upper floor. The foundations of the building are constructed to carry ten storeys, which will be the ultimate height of the building. The ground floor, which is 19 feet high, contains twenty stores, while the upper storey is divided into thirty-nine offices. Freight and passenger elevators provide good accommodation.

The building is steam-heated and modernly ventilated and lighted. Under the front sidewalk is a transformer vault into which both central station companies bring their 2200-vault, single-phase primaries and transform it down for 110-220 volt distribution, each company delivering half the required load. A duplicate set of automatic double-throw switches ensures continuity of service in case of service interruption to either company. A complete system of metering keeps accurate account of the power delivered to the different tenants by each company. Each store is provided with a separate panel in the basement, so that show-windows and signs can be separately metered. Corridor fixtures consist of ventilated bowls with high-efficiency Tungsten lamps, while the office fixtures, lamps with shades, provide a maximum lighting value of 8-foot candles, the store capacity, however, is considerably greater. A complete telephone system is also installed.

The illustration Fig. 2 shows a test being made on a reinforced concrete panel slab in the above building. The slab is 16 feet by 17 feet, and was subjected to a load of 70,000 lbs., equivalent to 250 lbs. per square foot. Under this load the slab was deflected three

Fig. 2—Concrete test. Curry Building, Winnipeg, Man

sixteenths of an inch, but returned to its original position when the load was removed. The test was made when the concrete was two months old: pig iron, cement, and stone being used to make up the load on the slab.

The building was designed by J. D. Atcheson & Company, architects, and constructed by the Sutherland Construction Company.

An interesting little booklet has just come to hand from the pen of W. P. Gerhard, C. E., 30 East 42nd Street, New York City, on the subject "The Water Supply of Country Houses."

Fig. 1 New Curry Block, Winnipeg, Man.

A Hollow Concrete Storage Dam

Comprises the equipment for a water storage and regulation scheme for the St. Francis River, P. Q.

The water-storage and regulation scheme proposed by the Quebec Streams Commission for the St. Francis River in the Province of Quebec has been described in some detail in earlier issues of the Contract Record. Contract for the storage dam has recently been let to Madden & Co., of Quebec, for $101,000. The following further notes are taken from a recent issue of "Engineering News."

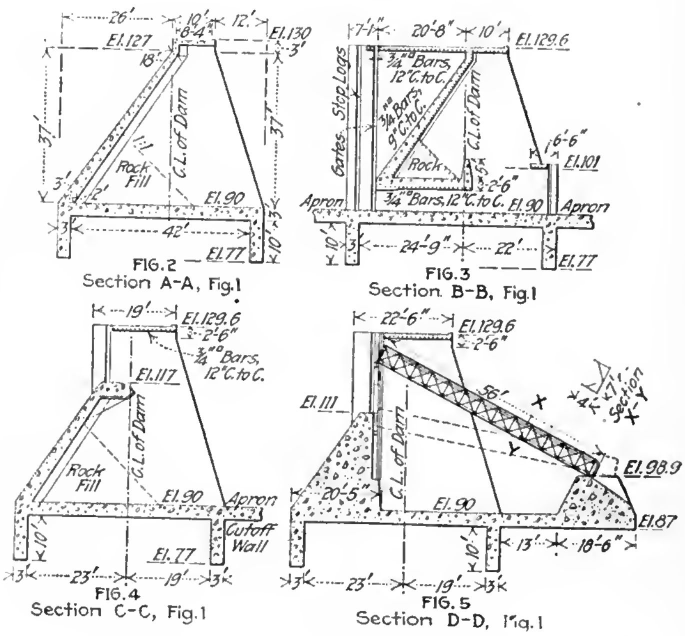
The regulation scheme briefly comprises a large storage dam at the outlet of Lake St. Francis and the purchase of about 4 sq. mi. of land to be flooded and power rights now held by individuals on Lake St. Francis and Lake Aylmer (just below). By raising the water level of Lake St. Francis 27 ft. the storage capacity will be increased by 438 sq. mi.-ft., making it feasible to regulate for a constant discharge of 600 sec. ft., which is an increase of 500 sec.-ft. over the present minimum.

The total fall along the river is about 900 ft., so that about 41,000 hp.-yr. additional is possible; but only 200 ft. available head is now utilized, so that the increase of power from the scheme will be about 6,000 hp.-yr. The present power users will be charged a sum per horsepower of increased capacity sufficient to cover the investment and maintenance of the storage scheme.

The dam itself, some typical sections of which are shown in the accompanying sketches, is to be of a hollow type, with reinforced floor slabs supporting a series of buttresses, which in turn on the upstream side carry a deck slab, flat on the outside face and arched on the inside (15-ft. radius). The buttresses also carry a concrete roadway.

The buttresses are 5 ft. thick and are on 20-ft. centres generally. In the gate section the buttress faces are vertical and have stop-log and gate grooves, as shown in Fig. 2. At the log sluice also the buttresses have a vertical face and show stop-log and log-slide grooves. The deck is carried on seats. The deck slab has the slope of the buttress faces, except for a vertical top section. At the log sluice a solid wall replaces the deck slab, as shown in the section, Fig. 5.

The floor slab varies in thickness from 15 to 36 in. The reinforcement is of ¾-in. square twisted steel bars bent so as to be 3 in. above the bottom of the slab at buttresses and 3 in. below the top of the floor between buttresses. The inner corner between the deck and floor will be filled with rock and faced with mortar. The two cutoff walls will be 3 ft. thick and 10 ft. high. At tht end panels they are joined and run as a bulkhead into the banks. Cutoff walls and

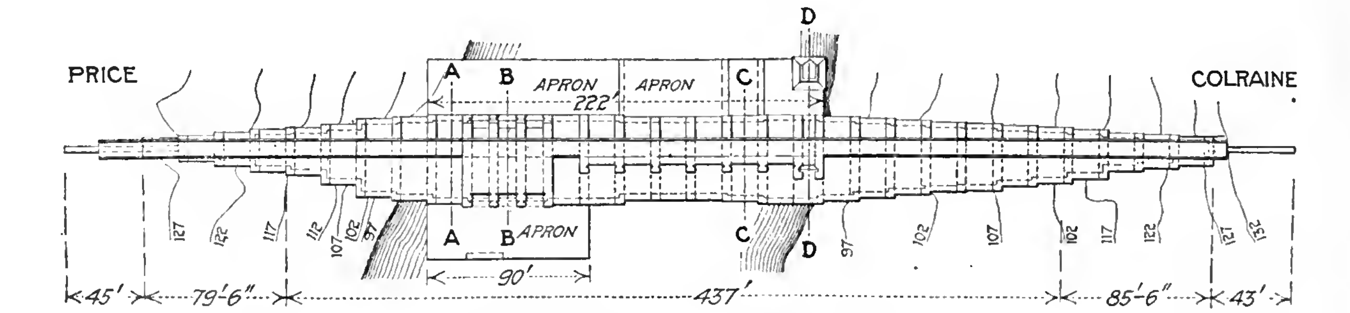


Sectional Elevations—show method of construction of hollow dam.

floor are monolithic. For floors, buttresses, aprons, etc., the concrete will be a 1:2½:5 mix, and for the deck slab and arches a 1:2:4 mix.

The Ottawa branch of the Canadian Society of Civil Engineers have made arrangements with the officers of No. 3 Field Company, Canadian Engineers, whereby members of the former branch may attend the lectures and drills of the latter. A special committee on military engineering has been appointed, consisting of the following members: W. S. Lawson (chairman), R. de B. Corriveau, G. G. Gale, Alex. Gray, and J. B. Challies.

The Warren Brothers Company, of Boston, Mass., have issued an attractive booklet dealing with Warren's portable asphalt plant; well illustrated.



Plan of Concrete Storage Dam at Lake St. Francis, P. Q.

Can. Soc. Civil Engineers Convene

30th Convention of Canadian Engineers at Montreal—Valuable Reports Received on Portland Cement, Bridge Specifications, Roads and Pavements, &c.—An Open Discussion on the Advisability of Extending and Enlarging the Scope of the Society to Include Every Section of the Dominion

The annual meeting of the Canadian Society of Civil Engineers, held at the Society's headquarters, Mansfield Street, Montreal, from January 25 to 28, was largely attended. Mr. F. C. Gamble, the president, was in the chair.

At the first session, held on Tuesday morning, the minutes of the last meeting were read and confirmed. This over, Mr. G. R. G. Conway proposed the following resolution which was received with the utmost cordiality, and which was carried unanimously amid repeated cheers:

> "That this meeting extends to Sir John Kennedy, past president; Sir Collingwood Schreiber, honorary member, and Sir Alexander Bertram, member, its heartiest congratulations upon the Order of Knighthood recently conferred upon them by his Majesty the King. The Society also wishes to place upon record its appreciation of the Royal and public recognition the engineering profession has received by the honors placed upon our distinguished members, who have always maintained the highest ideals of our profession. We recognize in the bestowal of these honors the growing public recognition of the engineers' influence not only in the arts of peace but also in the great ordeal the Empire is passing through at the present time."

Sir John Kennedy acknowledged the resolution on behalf of himself and the other recipients of the honors, stating that he looked upon the honors as a recognition of the engineering profession.

The President announced the receipt of the following cable, dated London, from General Armstrong, chief engineer of the Canadian Army Corps: "Please thank members for generous contribution Engineers hospital Fund. Greetings from all members serving Canadian Engineers to comrades at meeting." A reply was sent as follows: "Heartiest good wishes to all members at the front in defence of the Empire. May you speedily return to us victorious."

Annual Report

The report of the council was next considered. This showed that during the year there had been added to the roll 14 members, 66 associate members, 2 associates, 23 juniors, and 42 students—so that the total membership now stands 3,076. Twelve members of the society have been killed in action in France. The report also spoke of the very satisfactory progress made in connection with the opening of branches of the society, the last of which was formed at Regina under the present chairmanship of Mr. O. W. Smith. In July last a branch was organized in Vancouver, B. C. During the approaching session of the Dominion Parliament an effort will be made to have a bill introduced defining the term "civil engineer." Another important item taken up in the report is to the effect that consideration has been given during the past year to publicity matters affecting the profession of civil engineering. A circular is about to be issued with a view to instructing municipalities as to the advisability of employing only corporate members of the society, and it is also proposed to request corporate members, when advertising for assistants, to require that their candidates must be members of the society. A special committee appointed by council has under consideration at the present moment the best means of securing the appointment of engineers to civic boards, and commends the matter to the membership in general as one deserving of their support.

To Define "Civil Engineer"

Mr. G. A. Mountain, referring to the statement in the report that an effort will be made during the approaching session of the Dominion Parliament to obtain an act defining the term "civil engineer," suggested that a change in the name of the society might be desirable. As they were closely allied with the British Institution he thought the name Canadian Institute of Civil Engineers would be a better one than the present title. It would sound as if they were more of an educational institution, and they might thus be able to secure advantages from the Government in the way of reduced or free postage.

The President suggested that the matter be taken up at a later period.

Mr. W. McNab drew attention to the representations made by the Council to the Department of Railways and Canals, Ottawa, to the effect that the Society's specification for steel bridges should be adopted by the Dominion Government—a subject which is still under the consideration of the chief engineer of the department. Mr. McNab hoped that the representations would be more successful than others addressed to the Department.

Mr. W. J. Francis remarked that Governments were proverbially slow in making changes, and the Department wanted to carefully consider the matter before they made any change.

The President said his experience was that Governments considered a long time before they threw over their own specifications in order to accept those of the society.

Professor McLeod stated that the Department had written to the effect that the completion of the specifications on highway bridges would facilitate the consideration of the whole matter of the specifications.

The report was then adopted.

The remainder of the morning session was occupied by a discussion on the treasurer's statement and the report of the finance committee. The year's revenue totalled $22,079, and the expenditure $19,774, leaving a balance of $2,304.

Finance Report

Mr. R. A. Ross moved the adoption of this statement and the report of the Finance Committee. The latter called attention to the serious position in which the society is placed in consequence of the existing state of war, with consequent absence of members (30) at the front and the falling off of new membership because of conditions existing in engineering generally throughout the country; the result being a serious reduction in receipts for the next and probably the following years. During 1915 arrears of dues to the amount of $6,733 were collected, and it was calculated that $2,000 would be collected in 1916. It is expected there will be a shrinkage in revenue during the current year of about $7,000, and the committee outlined a number of economies which can be effected, with the result that in their view the revenue of 1916 will show an operating deficit of about $1,633.

It was stated in the course of a discussion which followed that the arrears for 1915 were $10,932, and that the total arrears, including the above, are between $17,000 and $18,000. It was also stated that a committee had decided to undertake a vigorous campaign in order to get additional members. The work of the Finance Committee was recognized as being satisfactory and the statement and report were adopted.

Discuss By-laws of Society

For nearly three hours, in the afternoon, the members discussed the question of the bylaws, the general status of the society, and the need for changes which would make for greater success, particularly in relation to the various branches. This is an old subject, which was brought to the fore by the British Columbia members, who desired an amendment of the bylaws.

Mr. E. W. Oliver moved the appointment of a committee to examine the bylaws and make recommendations for their amendment. He argued that the bylaws required amendment, and said that it could not be doubted that there was dissatisfaction with the affairs of the society. It was frequently said that the affairs of the society were managed for the personal edification and convenience of a group in Montreal. He had entirely changed his view on that subject since he had obtained fuller knowledge of the working of the society, and many of the Montreal members who had taken a leading part in the society should be thanked rather than criticized. He was in favor of radical changes in the bylaws, and he suggested that the whole proposition should be fully discussed by all branches in the Dominion.

Professor Haultain seconded the resolution.

Mr. J. A. Jamieson moved an amendment covering much the same ground as the motion. It favored the appointment of five to report upon the general policy, prestige and influence of the society, the means of raising the membership, the appointment of a permanent secretary, etc. The five members from the headquarters should be added to by representatives of the branches. He believed that the majority of the members were of opinion that they had only a small part in the affairs of the society, due to the system in operation. He thought that there was a certain lack of harmony between the members, and the appointment of such a committee as he suggested could only result in benefit to the society. On the question of a permanent secretary devoting all his energies to the society, the time would come when such an arrangement would have to be made.

Mr. Edwards (Edmonton) argued that the district should be the unit of organization in any new arrangement. Each district should elect its own members to the Council. It was difficult under present conditions to convince engineers that they should join the society.

Mr. H. R. Safford believed that the time had come to review their constitutional structure, and they ought to provide means for an extended discussion on the subject. Other and older institutions had experienced similar troubles, and he strongly endorsed action in best interests of the society.

Mr. C. H. Keefer was in sympathy with Mr. Jamieson's suggestions, believing that they would stimulate interest in the society in the outlying districts.

Mr. Conway supported the idea of reconstructing the basis of the society. They must co-ordinate the work of the society throughout the country. Good work was being done by the society throughout Canada, but it was not sufficiently known. There were many engineers outside the ranks who should be members of the society. He favored bringing into greater prominence the provincial bodies and branches. What was the use of electing provincial men to the council when the work had to be done by a few members in Montreal? He suggested the issue of a monthly magazine giving a record of what was being done by the society, and the appointment of an editorial committee to improve the publication of the Transactions. He favored appointment of a permanent secretary, and in this connection spoke of the excellent work done by Professor McLeod for many years.

Mr. R. F. Uniacke spoke in favor of some amendment to the constitution.

Professor Haultain said that the great trouble was the scattered membership, and a want of understanding.

Mr. R. A. Ross believed that the criticism was a healthy sign. What was required was a Council containing some young blood with new ideas. At the same time the present Council should not be sidestepped in any action which was taken.

Mr. F. W. Cowie said that undoubtedly amendments were needed in order to bring the constitution more in accord with present requirements.

Object of Society

Sir John Kennedy pointed out that the main object of the society was to improve their professional knowledge. They also wanted to unify the society as much as possible, and the tendency was to unify subjects rather than territory. It was a great thing to have a national society and they must endeavor to preserve this, and not to split it up into sections. He also remarked that in B. C. the main engineering work had been done by men who came into that province from outside. He urged members to get together in a practical way to improve the society.

After further discussion it was agreed that Mr. Conway, Mr. Jamieson, and Mr. Oliver should consult with a view to drafting a resolution agreeable to all three.

The reports of the various branches having been received, Prof. Brown moved and Mr. Francis seconded, the adoption of the report on Portland Cement. This was agreed to.

Report on Portland Cement

Specifications for Portland cement recommended by the committee for adoption by the society are given herewith. The requirements of this specification are uniform with those of the standard specification of the American Society of Civil Engineers and the American Society for Testing Materials. The standard methods of testing as approved by the American Society of Civil Engineers are also recommended for adoption, and the committee suggest that the council ask permission of the American Society to reprint their document embodying these standard methods.

Standard Specification for Portland Cement General Clauses

Definition.—Portland cement is the product resulting from the fine grinding of the clinker formed by the calcination of an intimate mixture of calcareous and argillaceous materials, in proper proportions, to which may have been added subsequent to calcination not more than three per cent. of other material.

Weight.—Unless otherwise agreed upon, cement shall be delivered in bags, each containing 94 lbs. net weight. Four bags shall constitute a barrel.

Packages.—All bags in which cement is delivered shall be made of good strong fibrous material, closely woven and in good repair when filled. The following information shall be plainly marked on each bag:—

(a) the net weight of cement contained therein,

(b) the name of the manufacturer,

(c) the brand of the cement, or the name of the mill in which it was manufactured.

Inspection.—All cement shall be subject to inspection and tests for quality, either at the place of manufacture or at the point of consumption. Every facility shall be provided and a period of at least 12 days allowed, for inspection and tests.

Storage.—Unless otherwise agreed upon, the contractor shall provide a suitable weather-tight building for the storage of cement, and easy access shall be provided for the sampling and identification of each shipment. The floor of the building shall be well raised above the ground and the space below it shall be well ventilated.

Testing

Methods.—All tests shall be made in accordance with the methods recommended by the Special Committee on Uniform Tests of Cement, of the American Society of Civil Engineers, accompanying the Final Report of that Committee dated January 17th, 1912.

Requirements

Acceptance or Rejection.—The acceptance or rejection of cement shall be based upon the following requirements, but cement failing to meet the seven-day requirements may be held awaiting the results of the twenty-eight-day tests before rejection.

Specific Gravity.—The specific gravity of cement shall not be less than 3.10. Should the cement as received fall below this requirement, a second test may be made upon a sample after ignition at a low red heat. The loss of weight on ignition shall not exceed 4 per cent.

Fineness.—The cement shall not leave a residue of more than 8 per cent. by weight on a No. 100 sieve, nor more than 25 per cent. by weight on a No. 200 sieve.

Time of Set.—The cement shall not develop initial set in less than thirty minutes, nor final set in less than one hour. Final set shall develop within ten hours.

Tensile Strength.—The minimum tensile strength of briquettes one square inch in cross section shall be as follows, and there shall be no retrogression in tensile strength within the periods specified.

Neat Cement

Age.	Tensile Strength.
24 hours in moist air	175 lbs.
7 days (1 day in moist air) (6 days in water)	500 lbs.
28 days (1 day in moist air) (27 days in water)	600 lbs.

One part cement, three parts Standard Sand

Age.	Tensile Strength.
7 days (1 day in moist air) (6 days in water)	200 lbs.
28 days (1 day in moist air) (27 days in water)	275 lbs.

Constancy of Volume or Soundness.—Pats of neat cement about three inches diameter, one-half inch thick at the centre, and tapering to a thin edge, shall be made and kept in moist air at 70 degrees F. for 24 hours, following which,

(a) One or more pats shall be kept in air at 70 degrees F. and observed at intervals for at least 28 days.

(b) One or more pats shall be kept in water at 70 degrees F. and observed at intervals for at least 28 days.

(c) One or more pats shall be exposed for five hours to an atmosphere of steam, above boiling water, in a loosely closed vessel.

The pats shall in all cases remain firm and hard, and shall show no sign of distortion, checking, cracking or disintegration.

Sulphuric Acid and Magnesia.—The cement shall not contain more than 1.75 per cent. of anhydrous sulphuric acid (SO_3), nor more than 4 per cent. of Magnesia (MgO).

A letter was read from Mr. W. G. Chace, chief engineer of the Greater Winnipeg Water District, raising certain points as to the report, and Prof. Brown replied to these in detail, stating that they had been considered by the committee. The report now becomes the standard specifications of the society.

In the evening a smoking concert was held in the society's rooms.

Visited Vickers Works

On Wednesday morning a large party visited the works of Vickers, Limited, Maisonneuve, the meeting resuming its session in the afternoon, when Mr. Oliver brought up a resolution as to by-laws, etc., agreed upon. It was to the effect that the Council be instructed to appoint a committee to study and report upon a policy for increasing the prestige, influence and organization of the society and to revise its by-laws. The committee is to consist of representatives of each district. This was carried.

A letter was read from Mr. J. G. Legrand, of Winnipeg, referring to the part of engineers in the war, and expressing the opinion that engineers should make suggestions to the Government, with a view to improving our efficiency in fighting our foes. He also urged that in view of the common danger petty politics should be repressed.

Arising out of this letter, Mr. Conway raised the question of assistance by the Society in training engineers who desired to become officers of engineering corps. Mr. Francis replied that the council had had this matter under consideration, and had co-operated with the engineers' corps which had gone to the front and also with the Institution of Civil Engineers. Mr. Francis took the opportunity of deprecating the pessimism which had tinged some of the speeches. On the contrary he said there was no decreasing interest in the society. Mr. Ross added that the Council had offered the services of the Society to the Government in any direction thought desirable, but had been turned down.

The conservation, electro-technical, roads and pavements, steel bridge specifications, and educational requirements were laid before the meeting.

Report on Steel Bridge Specifications

The chairman, Mr. P. B. Motley, stated that the specification for steel railway fixed spans had already been issued, but owing to the great diversity in practice, as well as in the details connected with the subject of highway bridges, the committee had found it impossible to complete this specification in time for the annual meeting. The draft, however, will be ready for preliminary discussion by the branches at an early date, and should be ready for submission at the next annual meeting.

Report of Electro-Technical Committee

Dr. L. A. Herdt, chairman, reported that owing to war conditions the international congress planned for September of last year could not be held at San Francisco. A conference had been held in London in March on the rating of electrical machinery, and copies of the British standardization rules for electrical machinery as adopted at that conference will shortly be available for distribution in Canada.

Report of Committee on Roads and Pavements

The chairman of this committee, Mr. W. A. McLean, stated that in the opinion of a majority of his committee it is not desirable at the present time to prepare standard specifications for roads and pavements, though consideration might be given to specifications for certain materials. They desired to impress, however, that there is a great waste of experience in the matter of road construction and paving at the present time due to lack of any organization to assemble the results of such experience. As a result it semed desirable that the committee should assume the duty—first, of determining uniform traffic standards whereby wear can be more definitely compared, and, second, of the compilation of the history of individual pavements. To this end the co-operation of engineers throughout Canada would be necessary so that each should supply from year to year definite details of such pavements as came within his particular knowledge. Appendix 1 and Appendix 2 were attached to the report as suggested forms which would be suitable for the collection and filing for reference of the desired information.

Interesting reports were also presented by Mr. James White, chairman of the committee on Conservation, Mr. Ernest Marceau, chairman of the committee on Educational Requirements, and Mr. J. M. R. Fairbairn, chairman of the Library and House committee.

The President then delivered his retiring address, which in part said:

Mr. Gamble's Address

The past year has been one of stress and anxiety. The British Empire has been engaged for eighteen months in the greatest struggle in the history of the world with a nation which for over forty years has been unsparing in preparation for imposing upon the world by force its system of civilization and "Kultur." Notwithstanding the serious handicap of unpreparedness under which the Empire entered upon this war, the British Army under the unsurpassed guardianship of the Grand Fleet, and supported by contingents from the Overseas Dominions, has withstood the violent attacks of the enemy in Flanders and France with courage and valour. It is not too optimistic to say that the ultimate end shall be the triumph of British principles of liberty and justice. To assist loyally in the task thus imposed upon the Empire three hundred and sixty-three members of our Society (ten per cent. of the total membership) have given their services freely, of which number thirteen have so far made the supreme sacrifice. We honor those who have died that the Empire may live, and extend to their relatives an expression of our admiration and deepest sympathy. While the memory of their deeds will remain in our hearts as long as we live, it is but fit and proper to commemorate by a tangible token their noble patriotism and unselfish surrender of their lives.

In one way the Society has already marked its appreciation of this by remitting the annual dues of members actively engaged at the front. This should meet with the unanimous approval of members.

We have to mourn the loss by death during the past year of sixteen members, including juniors and students. Of these thirteen were killed in action, to which a previous reference has been made. Of the others special mention should be made of the late Mr. T. C. Keefer, C. M. G., first and tenth president of the Society and afterwards Honorary Member, and of Sir Sandford Fleming, who became a member in 1896, and was made an Honorary Member in 1908. These gentlemen conferred a marked distinction upon the Society, having acquired by probity, eminent ability and usefulness, world-wide reputations. Their careers must be an inspiration to the younger generation.

There are many Civil Engineers living in the Dominion of marked ability who still hold aloof from us. These can only be induced to join by raising the Society to its proper plane of usefulness, and increasing its sphere of influence. Solicitation to join us must be avoided as an undignified and weak expedient. It is quality not quantity that is desirable. A most essential factor in bringing about the increase in our membership, attracting to us the most accomplished Civil Engineers, is the firm and courageous carrying out of "The Code of Ethics" adopted by the Society.

The profession of Civil Engineering, owing to its somewhat uncertain position, having no legal standing, differs from other professions which enjoy the law's protection, and, therefore, there is the greatest necessity for members to practise the virtue of loyalty to each other and to the profession. If each member realizes his responsibility in this respect public esteem and confidence will increase.

The Council during the past year has been active in bringing to the attention of governing bodies, Federal, Provincial and Municipal, matters of importance and intense interest to the profession of Civil Engineers practising within the bounds of the Empire. Although no direct beneficial results have been achieved so far, we have no reason to be discouraged. In the coming year, if the past representations are firmly and fearlessly persisted in, some measure of success will without doubt attend our efforts. We are not demanding anything unreasonable or beyond our rights as citizens. We should resent firmly any adverse inference to be drawn from the continued indifferent treatment meted out to the profession by public bodies in Canada. The amelioration of the disabilities under which we labor at present is one of our just demands.

The Society through the Council might well direct its energies towards securing the adoption by governments, for Civil Engineers in the public service, of a standard of qualifications. The Institution of Civil Engineers took this question up with the Imperial Government, meeting with a sympathetic response, and this Society should not hesitate to move in the same direction.

(For List of 1916 Officers see page [illegible])

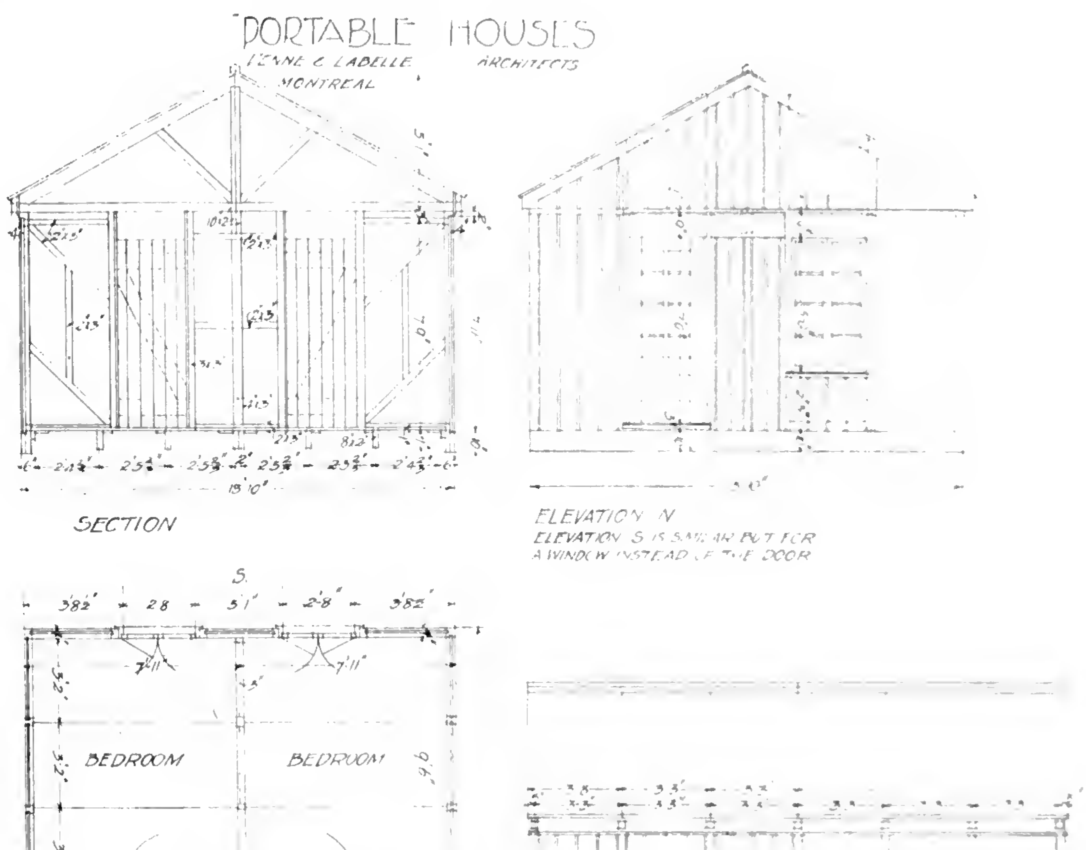
Portable House for Proposed Gift

The following is a brief description of the plans of a wooden portable house, fifty of which the Canadian Timber Products Association propose donating to the devastated portions of France and Belgium.

The figures herewith show the plan, elevations, and an isometric perspective of the design chosen. The houses are built of lumber, using a roofing material such as tar paper, asphalted paper, rubberoid, or ready roofing, with an interior trim, if desired, of beaver board.

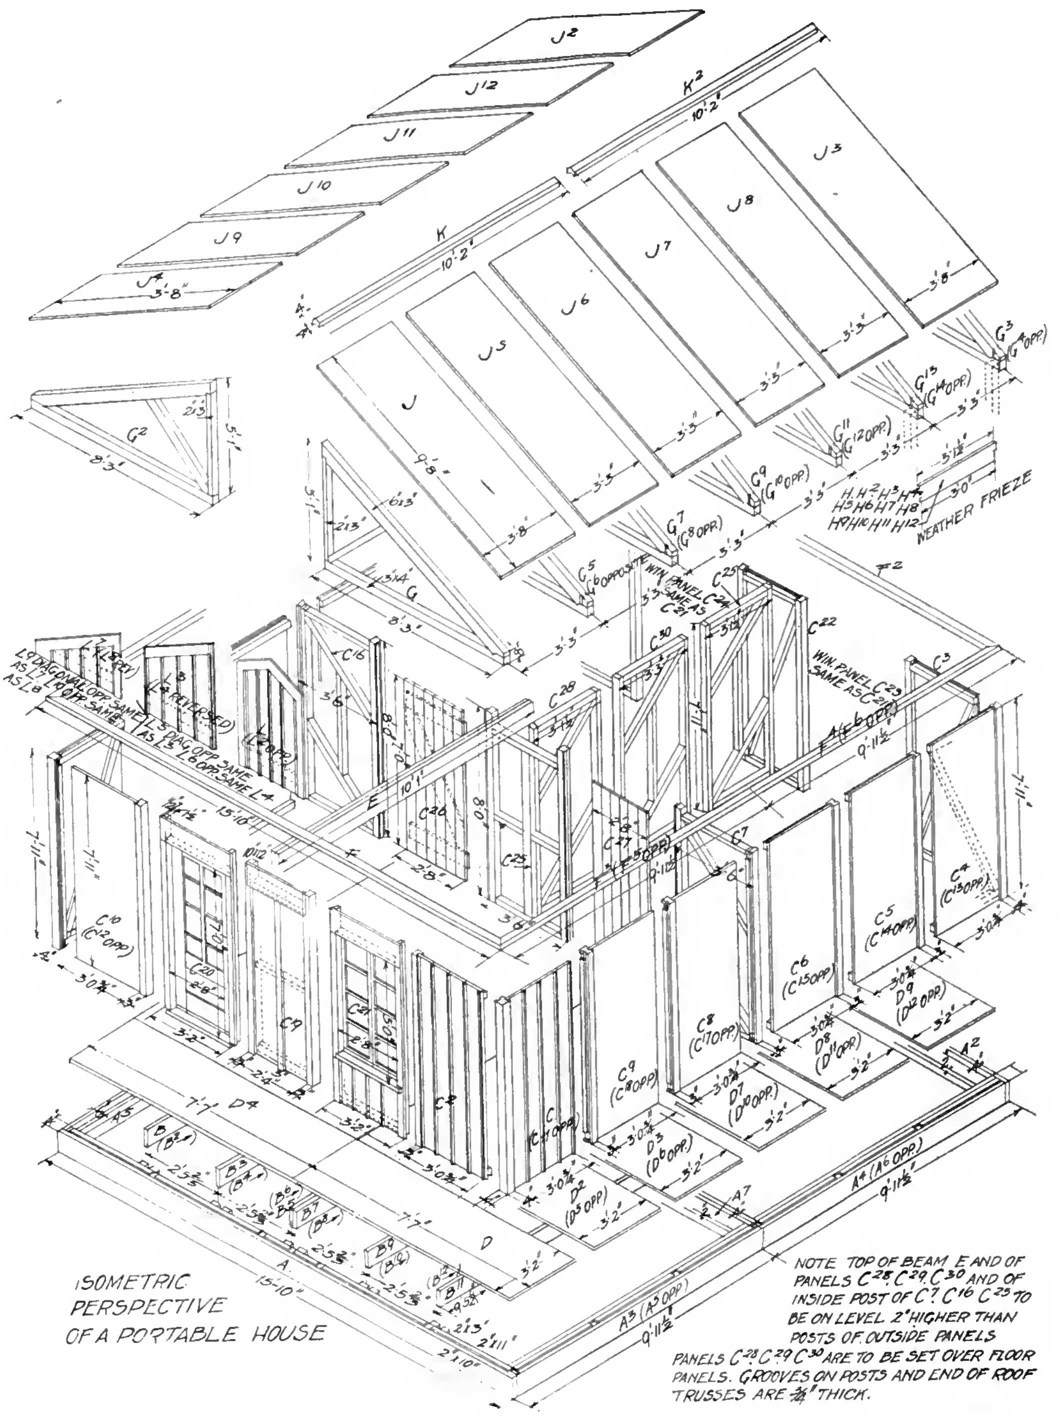
The structure is 15 ft. 10 ins. by 19 ft. 11 ins. plan dimensions, approximately 14 ft. high, contains three rooms, with a uniform height of storey of 8 ft., and has three windows and a door. The front room, or hall, is 9 ft. 6 ins. by 15 ft. 5 ins., while the other two rooms, which may be used as bedrooms, are both 7 ft. 7 ins. by 9 ft. 6 ins. inside dimensions.

The building is as simple and symmetrical in design as possible. The front elevation contains a door and a window, and the rear elevation is similar but for a window in place of the door. Both side elevations are of similar design, each being built of six 3 ft. 3 in.



Suggested plans of Portable House for Proposed Gift from Ontario Lumbermen to France panels grooved ready to fit one another and to receive the top and bottom rails. The floor is made of 1-in. tongued and grooved boards, dressed on the wearing surface, laid in six sections each 3 ft. 2 ins. wide, nailed to five 2 x 8 in. joists. These joists rest on 2 x 3 in. blocks nailed to a base girt composed of a 2 x 10 in. plank 15 ft. 10 ins. long, spiked to a 2 x 11 in. plank which is notched to receive the uprights. The roof is built in two halves; each half is made of a 3 x 4 in. tie beam framed and notched to the main rafter and to the 2 x 3 in. half king post. The rafters are made of 3 x 6 in. material framed to the tie beam and half king post. The roof, similar to the sides, is put on in panels the same width as the side panels, made of 1-in. tongued boards nailed to cross-pieces. The door is 7 ft. 1 in. by 2 ft. 9 ins., built of 1½ in. material with one flush panel, and prepared to receive eight panes of glass. The three windows are 5 ft. by 2 ft., made of 1½ in. material with two sashes prepared to receive four panes of glass.

A detailed bill of quantities of the material necessary for this portable house has been drawn up. It is proposed to have the makers mark each piece with a distinct sign or letter, tie all similar pieces together, for the sake of order and method in shipping, and to secure thorough, easy, and rapid assembling by inexperienced hands. It is roughly estimated that these houses may be produced at an actual cost of $150.00.



Isometric perspective of Portable House planned for presentation to France.

Large Concrete Cantilever Trusses

Support Sewer over half mile of river flats at Victoria, Australia

EVIDENCE of the possibilities of reinforced concrete construction is strikingly shown in the new cantilever truss design for carrying a reinforced concrete sewer over a crossing of nearly a half-mile in length of river flats in Australia. A brief description appears in a current issue of Engineering Record, and the accompanying illustrations give a fair idea of the unusual character of the structure.

The structure is located in Victoria, Australia, and was adopted after alternative designs in both steel and reinforced concrete had been made to carry the sewer, which is part of the recently installed sewer system of Geelong across the River Barwon and the river flats.

Near view of foundation showing spread of cantilever.

The total length of the structure is 2,424 feet, consisting of thirteen spans of 176 feet and one span of 136 feet. The suspended spans are 40-ft. girders, free to move at one end. The cantilever design is economical and has a further advantage in the fact that all temperature variations can be provided for by horizontal movement at expansion joints. This consideration ruled out the possible alternative of a series of arches, in which temperature movements are vertical and would create a series of undulations very undesirable, because the grade of the sewer is only 1 in 2,500.

The distance between cantilever trusses is increased toward the piers in order adequately and economically to resist the horizontal wind forces. The lateral bracing consists of transverse struts with knee braces to the main chords, as seen in the photographs.

The reinforced-concrete pipes are oval in form and cast in 8-ft. sections, which correspond to the 8-ft. panel lengths of the trusses. Cross beams and struts thus support the pipes at their joints. The same forms were used for the pipes on the structure as for the main sections of the sewer.

The reinforcement throughout is of ordinary steel rods, the full tensile strength being developed at the splices by laps; in no case are they mechanically connected. The rods in the upper chord are arranged in concentric rings, the laps of which break joints along its length. The diagonals are in tension, and the ends of the rods through them are accurately pent around the rods in the upper and lower chords.

A footpath is provided throughout the whole length, and the details of its treatment add very considerably to the appearance of the work. The handrailing of the footpath is sufficiently reinforced to act as a girder. It was thus possible to maintain a continuous footpath form.

The John V. Gray Construction Co., Ltd.

It has just been announced by Mr. John V. Gray that he has severed his connection with the firm of Wells & Gray, Limited, Engineers and Contractors, Toronto, and has organized a company named the John V. Gray Construction Company Limited, with head office at 346 Confederation Life Building, Toronto. This firm is now prepared to give estimates and tenders on and carry out contracts for the erection of all kinds of buildings, specializing on modern reinforced concrete, brick and mill construction buildings for all purposes as well as cold storage and packing house buildings. In the circular letter just issued by Mr. Gray he points out that he has had nearly thirty years practical experience in all kinds of construction work, and that his future policy, as in the past, shall always be to exercise strict honesty in all his dealings, to do the best gradé of work and to give those with whom he deals as nearly as possible perfect satisfaction. Those who know him best will appreciate most his sincerity and ability in this matter.

Cantilever Trusses and Cross Beams support oval pipe Reinforced-concrete construction throughout.

Montreal Builders' Exchange Annual

The annual general meeting of the Montreal Builders' Exchange was held in the reading room of the Exchange, 52 Victoria Sq., on Monday, January 24th, the president, Mr. John Quinlan, in the chair.

In his presidential report Mr. Quinlan stated that while the Exchange during the past year had not undertaken any work of a specially aggressive character and had continued its policy on familiar lines, yet its membership had been consolidated and its finances strengthened. The membership now embraced all classes of firms engaged in the building trades and

Mr. John Quinlan, re-elected President of the Montreal Builders' Exchange.

had become more and more recognized as the official organ of the building interests of the city. The year 1915 would be long remembered as an extremely trying one for the building trades, especially in the city and island of Montreal. That the members as individual business organizations had been able to keep moving upward, if only in a small degree, was due to their natural ability to change their methods to suit altered conditions, to develop their business along various new lines afforded by war conditions, to supply material at prices which afforded a fair legitimate profit only, to deal with labor in a generous spirit, having due regard to all factors which entered into the wages problem, and finally to bringing into their several organizations the latest modern methods, the use of up-to-date labor and time-saving machinery, and by maintaining an honorable reputation for skill, honesty, and responsibility.

In the immediate future, the building operations in Montreal would proceed along lines different from those that had obtained in the past. The city at present had sufficient office accommodation for years to come; he thought, however, they would see a considerable extension of structures suitable for manufacturing and industrial plants. Of the higher priced residential buildings there were more than sufficient for immediate needs, but there was a steady demand for homes of a moderate price and especially of the cottage or semi-detached villa type, and if the increase in population took place which was so confidently predicted in several authoritative quarters, they might expect to share abundantly in the work of erecting homes for the people. Mr. Quinlan suggested that there was room for a central library, museum, a public hall suitable for great political meetings, etc., a civic art gallery, a winter garden and concert room, and many and convenient comfort stations.

On the subject of the civic fair wage schedule, the delegates of the Exchange were able to convince a civic committee of the unfairness of the wages proposed, but the schedule was finally adopted. For the current year it had been decided that the Builders' Exchange and kindred organizations and the various labor unions be consulted before the schedule was drafted, and this would make for more equitable terms and more harmonious working.

After referring to the means taken to promote Federal free labor bureaus throughout the country, Mr. Quinlan spoke of the Industrial Disputes Act and also efforts made, with others, to bring about a reform in the Government of Montreal.

A committee had been appointed to study the proposed bylaws regulating the erection of scaffolds in the city.

During the year the relations between the Exchange as employers and the workmen had been most harmonious. He noted the greater ease with which organized labor and the various trade sections of the Exchange approached one another and sought to arrange their differences without the intervention of outside parties.

In the near future the Exchange should busy itself in formulating some scheme to take the place of the old trade apprenticeship system, which many observed with regret was passing away, if it had not wholly done so, in the city. In the years to come the workshops would be wholly dependent for their supply of skilled labor on outside sources and capable youths of the country would find their energies restricted to a narrower field. It was possible, he suggested, to draft a plan on lines similar to those adopted in some older countries of the world, modified of course to suit local conditions, whereby sturdy boys could obtain their practical training in shops or on construction works and their theoretical training and knowledge of the principles underlying the operation of their trades in schools specially organized and equipped for this purpose. The provincial Government had established throughout the province technical schools, which were doing excellent work, but if the greatest good was to be obtained there must be developed a plan whereby the school and the workshop could be brought into still closer contact.

A committee had been appointed to examine the whole subject of greater co-operation between the members of the exchange and the members of affiliated bodies.

Mr. Quinlan concluded by expressing his appreciation of the cordial assistance given him by the directors, and of the harmonious relations which had prevailed.

Mr. D. K. Trotter, the secretary, submitted the financial statement and report showing receipts of $5,318.30 and expenditure of $5,030.03, leaving a balance of $288.27. He made a number of suggestions for strengthening the exchange by the addition of new members and by securing various trades sections organized and affiliated with the Exchange.

A long discussion on the civic paving law followed. This was participated in by the President and Messrs. J. H. Hand, J. J. Roberts, E. W. Sayer, F. B. Locker, J. P. Anglin, and John Allan. The question at issue is as to whether the city or proprietors should pay for paving improvements and in view of the sharp divergence of opinion it was decided to appoint a date for a special meeting to discuss the subject, before which date all the members of the exchange should be invited by special circular to express their views, and in the meantime to have all the information on the subject of the paving laws ready to hand.

The election of officers resulted as follows:—President, Mr. John Quinlan (re-elected); 1st vice-president, Mr. E. W. Sayer; 2nd vice-president, Mr. J. P. Anglin; directors, Messrs. Walter Bonnell, representing general contractors; Alex. W. Bremner, suppliers of building materials; Alex Charette, master plumbers; Robt. F. Dykes, cut stone contractors; J. W. Graham, mantle and tile dealers; John H. Hand, Wm. Irving, and W. C. Munn, general contractors; W. E. Potter, master painters; W. E. Ramsay, suppliers of roofing materials; J. J. Roberts, carpenters and millmen; and J. E. Walsh, master plumbers. The trade representatives in the above are Mr. Alex. Charette, representative director appointed by Master Plumbers' Association, and Mr. J. W. Graham, representative director appointed by Mantle & Tile Dealers' Association.

England's Malady—The Party System

By Cosmo Hamilton

One night, with the memory of the South-African War still stamped upon his leonine face, a little old man whose small eyes were charged with a kind of prophetism went into his study, threw down the notes of a speech that he had just delivered in the House of Lords, sank rather feebly into a chair, and burst into tears.

There were two younger men in the quiet room, tall, wiry men on whose faces and figures discipline had laid its restraining hand—soldiers both. Their sympathy was inarticulate. And then the old man spoke.

"Curse those fools!" he cried. "Curse them! They won't listen to me. I am a mere damn' soldier. I am talking facts, and they know it; but the system, that unique and criminal system of party politics, renders them absolutely impotent even if they desired to take advantage of the evidence that I have flung at their heads. I told them that the British army has only just escaped being whipped by a pack of farmers, that the flower of English manhood, unready because of these little clever people who sit at Westminster, has manured the wide stretches of the veldt, where their gravestones are meaningless. Will they take a lesson from this two-years' national disgrace? Will they organize the whole Empire by a form of compulsory service to meet the menace of the great Teuton machine which every day is being perfected for its inevitable use? No; I tell you, no. And yet, by God! there are a few men sitting in the House of Commons not yet so warped and twisted by the dishonesty of the party system that deep down in what remains of their souls they know that my stammering words are true. 'Compulsory service? Yes, that is the solution,' they say; 'but what kind of fools shall we be considered by our friends if we sacrifice our political careers for the sake of patriotism?' No, it's no use. Stop me ever from getting on my feet again. I am hurling my old body up against the brick wall of a political system that one of these days will place England under the feet of a determined, self-sacrificing, industrious and brutal enemy."

That little old man was Field-Marshal Earl Roberts of Kandahar.

* * *

Dinner was over; the servants had left. The thin smoke of cigars and cigarettes rose up to the gilt ceiling of the large, dignified room when the laughter and conversation of the men whose faces and figures formed the subject of caricatures in the English papers suddenly died away. The host, a bearded man with a high forehead and heavy bovine eyes, leaned forward. In his rather fine white hand he held a thick amber cigar-holder, which he used as a sort of baton to enforce his words.

"Gentlemen," he said in the peculiar guttural voice which was known and loved in many strange parts, "look out! I have asked you here on my return from Germany to say to you, look out! A colossus is stretching himself. Every great muscle of his arms is taut and hard. Every little cell of his great brain reverberates with two words only, 'Der Tag.' . . . . We live in a false security here. We are a democracy which tolerates a monarch. You, gentlemen, are our autocrats. Each one of you is the king of England. What are your majesties going to do? Are you going to continue to play Canute and hold up your hands to the waves and say, 'Back!'? Are you going to continue to sit within the apparently impregnable walls of your party system? Because, if so, the security of this kingdom and your little crowns is not marketable. There are no bidders. I say to you again, look out!"

That man was King Edward VII. of Great Britain and Ireland.

* * *

There was only one policeman outside that little, dull, unpretentious house in Downing Street in which much regrettable history has been made, and from which one generation after another has been misgoverned and misled by premiers and their satellites. On his chest were the ribbons of medals won in India and South Africa, and in his eyes there was the look of a man who fears that he is about to face unutterable disgrace.

He has watched one member after another of the British cabinet scamper up with white lips. From where he stands he can see the complicated system of wireless telegraphy on the roof of the Admiralty. He knows well, like every other man of the nation to which he belongs, that a message has been framed to be despatched from those wires to the great ships that lie waiting off the coast. He knows also that the hands of the army and navy are held by the grip of the party system, and that the agreements of his country with her allies may be broken, to her everlasting shame, by those frightened, panic-stricken men who have rushed up from their country houses to attend the cabinet meeting within.

There sat Mr. Asquith, the prime minister, with ashen face and hands shaking like a man with palsy. All round the table were seated the men who had trifled with their trust. Their teeth were chattering. They were face to face

*In Century Magazine.

at last with the truth which they had dodged and refused to recognize.

"Why should we fight?" they stammered. "We are a peace-loving nation, unready for bloodshed. Let the others fly at one another's throats, and while they kill and devastate we will grow rich. Are we not a nation of shopkeepers?"

"Listen!" said Mr. Asquith.

From all parts of Great Britain and Ireland—yes, Ireland—there rose an ever-increasing rumble of passionate protest, like the breaking of huge waves upon rocks. Bugles seemed to ring out, and from every town and hamlet there appeared to rise up millions of hands. Near by a bell was tolling.

Mr. Asquith looked up and all round, catching the troubled eyes of his henchmen.

"Oh, my God!" he said, "our servants have become our masters. They demand that we shall fight. Gentlemen, the party system is dead."

* * *

The party system! The House of Commons is divided into two bodies. On one side of it sits the party in the majority, on the other side the party in the minority, and over them both the Irish. The House of Commons purports to represent a great country whose history gleams with the heroic results of individual effort. The constitution of all the men under the roof of that House is the same. Whether they call themselves Conservatives or Liberals, they are not there for reasons of patriotism. They have entered politics for the same reason that takes men to the stock-exchange and upon the stage—for money and for advertisement. On both sides there are men who own newspapers, run simply for the purpose of grinding their little axes, in which they may hurl sham invective at their fellow-conspirators and write columns of self-praise. On both sides there are lawyers who have tacked on politics to their profession so that they may stand in the lime-light, pick up the plums, and manipulate commerce to their own benefit. On both sides there are bankers and publicans, journalists and company-promoters, city merchants and the poverty-stricken relatives of the great political leaders, who will obey orders, answer the party whip, and sell their souls for a mess of pottage. On both sides there are little creatures from the back alleys who have been educated to politics as a means of livelihood, and who are perfectly willing to assert that black is white or vice versa whenever they can gain by doing so. The majority are, ipso facto, the enemy of the minority, and the Irish hate them both; but the minority, majority, and Irish are all working together for their own ends. They may call themselves Conservatives, Unionists, Radicals, Liberals, Nationalists, Fenians, Anti-Vivisectionists, Little Englanders, or any one of the dozen meaningless names which have grown into the English language, but they remain mercenaries and parasites, the manipulators of a party system which is a cunningly built-up conspiracy to mislead the country, misrepresent its voters, and provide places for the incapable sons of peers and yearly incomes for specially chosen men whose integrity has been proved to be easily bought, and whose eloquence, like that of a criminal lawyer, is as ready to be used in defense as in prosecution.

In a word, the party system of British politics is the one corrupt thing in the constitution of that nation. The House of Commons has become the happy hunting-ground of a dozen great families whose members pass into it from time to time by the same right that men pass into the business firms of their fathers. They are all partners in a great swindle, and their clerks and henchmen, hired from the law, the universities, the factories, and the streets, vary only as their masters see fit. Those masters, nearly equally divided on both sides of the House, agree from time to time to take the reins of office, paying themselves large salaries, large pensions, giving places only to those men who have been most obsequious and most eagerly dishonest. They juggle with the votes of the country, with their tongues in their cheeks. They are past-masters in card-sharping and the three-card trick. There is not one man among them with the faintest gleam of imagination, patriotism, or understanding of the characteristics and spirit of the race whom they bluff by inheritance. Yes, there is one—the Mark Antony of the House of Commons, the little Celtic man whose name is Lloyd-George, who possesses the three gifts that go to the making of a great charlatan—a pair of wonderful eyes, a sense of impish humor, and that touch of exaltation which stirs men to hysteria. He is the Pied Piper of politics, the man whose little flute can draw from their dark places the laboring parties of the United Kingdom. He is the great democrat who has organized a bureaucracy more autocratic than anything in Russia. He is the king of charlatans.

England is a free country, a democracy which tolerates a monarch, and is governed by a royal family of hereditary politicians supported by a nation of slaves.

Let a young man enter Parliament big with a desire to get things done, imbued with honesty of purpose, honest enthusiasms, honest patriotism, and a great wish to devote his energies, abilities, and all his time to the amelioration of one or other of the evils which have been left coldly alone by the party system, and he goes into a mausoleum of broken lives over the portals of which is written the terrible legend, "Give up hope, all ye who enter here." The result of his temerity is inevitable. He has either immediately to sacrifice honesty to selfishness or to rush back into the world once more to breathe uncontaminated air and to hurl invective, unnoticed, uncared-for, at the men who year after year deliberately stand in the way of progress and with the utmost cunning lay stone after stone upon the great dam which holds back the waters of improvement and incloses in wonderful security the confidence-men who live upon the credulity of the British public.

The party system of Great Britain is responsible for the degeneracy of a great nation. It is responsible for the unemployment of its working-classes, for the tyranny of its trades-unions, for the sense of injustice which, but for Germany, would have seen insurrection in Ireland. Finally, it is responsible for the unforgivable devastation of Belgium and for all the bloodshed, for all the hideous waste of life, money, material, and for the chaos of civilization under which, in pitiful attitudes, the fathers of the next generation lie crumpled and dead.

Every widow, every orphan, every maimed man in Europe to-day; all those poor boys from Canada, Australia, and New Zealand; every Frenchman, Belgian, Indian, Russian, Italian, African; every man who has sprung to arms, left his civil work, his little patch, his quiet haven where the patter of children's feet has been the music of his life, has to thank the English party system for this war. Countries as crippled as their sons, who have crept back like whipped dogs to a kind of life, will for ten, twenty, maybe a hundred, years hence have to thank the English party system for this hideous, unnecessary, preventable war. If there is yet one spark of remorse in the little souls of the men who have sat so long at Westminster greedily taking their salaries for the non-performance of their duties, then the quiet lunatic asylums which stand among the silent poplars of English country-sides must soon be full. If not, if their long service to dishonesty has eaten into them, if they see no shame in having permitted their country to slip into unreadiness and inefficiency, these little, petty harpies, these hypocritical self-advertisers, may have the satisfaction of wallowing in a sort of triumphant pool of exaltation; may congratulate themselves on having achieved an act of incendiarism so frightful that the bloody glow of its flames lights up every corner of Europe.

Mr. Balfour, the theorist, the gentle, gentlemanlike university professor, upon whose gravestone will be carved the words, "Nothing have I ever achieved"; Mr. Asquith, his own worst enemy, whose famous, "Wait and see," will be forgotten and forgiven only when the beautiful towns of Belgium shall have risen once more; Mr. Winston Churchill, the inefficient hustler, who breaks, like a bull in a china shop, through the work of experts, and who will be remembered by posterity only for his comic hats; Sir Edward Grey, the imitation sphinx, who has never yet in all his political life understood the very rudiments of diplomacy; Lord Haldane, whose vanity is like that of the toad and whose credulity is no less than that of the bumpkin who goes to the race-course and falls an instant victim to the confidence-man, —these men, and all their satellites without one exception, have quietly, steadily, and persistently made it possible for German militarism, German chemistry, and German effrontery to cause England to be the one country on earth whose name can never be mentioned again throughout the ages without raising the bitter ire of her friends. Oh, my God! to think that the little old man, scarred and battered with the wars of his country, left alive surely by an all-pitying Diety so that his magic voice might sink into the hearts and brains of his countrymen to prevent the sacrilege of civilization, should have lived in vain! His warnings and his appeals, which stirred the English nation from coast to coast, were scoffed at or ignored by the English politicians. The monthly reports of the secret services, all proving the criminal folly of the policy of laisser-faire, have been docketed away. The facts which have been plain to all the world, and caused France to strengthen her army and cut the terrible figures, 1870, on every one of her bullets. have been scorned by the English politicians. Instead of taking advantage of the anxious readiness of the country to subscribe to a system of compulsory service, they have steadily weakened the army and would have scuttled the navy had not their rudimentary knowledge of the nation's temper told them that such an act would have brought about a revolution. They knew of Germany's settled intention of declaring war when armed to the teeth. They knew that the day was drawing ever nearer when the peace of Europe would be broken by the roar of artillery. Every conceivable piece of evidence that daily accumulated on their desks made that fact plain and unanswerable. How, then, did they intend to act when overtaken by the inevitable? Take one look at the journal subsidized by them and find the answer. Not caring for or appreciating the country's sense of honor and pride, they intended to break their treaties and stand aside. They were going to say: "Let them fight who care to; we are unready, unwarlike. We will provide the loans at a high rate of interest and the ammunition at a price." Therefore I cry out aloud the sentiments of all true Englishmen when I say that the English party system is responsible for the war; because, had we been able to place a great army in Belgium to resist the German assault, there would have been no war. It was only because Germany knew of England's unreadiness, and was in the counsels of England's politicians, that she sprang at Belgium's throat.

> The mills of God grind slowly, yet they grind
> exceedingly small.

The germ of suicide would grow and grow in the brain of the thinking man did he not passionately believe that God does not intend this war to be just a hideous fracas, a blood-drunken orgy. The day will come when the warring countries, flung at one another by the leading villians of greed and selfishness and dishonesty, will flick the blood out of their eyes and ask one another the meaning of it all. The maimed and broken of all sides will look to see, in compensation for their lost limbs, the improving hand of the Master upon the churned-up earth. Out of her ruins France will rise with prayer upon her lips; Belgium, with her arms bared for the rebuilding of her smashed cities; and Russia with tears in her heart and brotherhood in her hands. In what manner Germany will be touched who can say? As for England, she, like a creature miraculously risen from the operating-table, will look out on the future with humbler eyes and a thankful heart. The cancer of the party system will have been cut out forever.

Looking through the smoke, I can see the House of Commons occupied by a small committee of unpaid men—business men, honest men. They would shudder to be called politicians. Their ambition is to earn the title of patriots. They belong to no party. They are the servants of the nation. They will not govern the country; they will guide it. They will pursue the same principles and methods for the restoration of her commercial strength as are employed by a committee of liquidation appointed by the court of bankruptcy to a broken business concern. They will run Great Britain in the simple way in which a great railway company is run, and their shareholders, the nation, will be content to read their statements of progress and receive their dividends. Phoenix-like from the ruins there will have risen honest men, and there will be no comfortable corner on this earth for those outcasts who once gambled with a nation's soul for money.

Winnipeg Sleet Storm Brings Down Towers

A sleet storm in Winnipeg, Man., early last month, resulted in the breaking down of one tower on the lines of the city's municipal transmission system, about 30 miles from the city, and caused about 2 miles of wire to be thrown off the towers of this system. The transmission line of the Winnipeg Electric Railway Company was broken in two

Sleet storm doubles up one of Winnipeg municipal towers.

places, but the damage, which was not so serious, was repaired by night time. The weather conditions were exceptional for that region, the sleet being of such thickness on the wires that the over-all diameter exceeded 2½ in. The cables of the municipal system have a total area of 275,600 circ. mils and are strung on towers such as the one shown in the accompanying illustration alternating with braced structures, spaced 600 ft. apart. The insulators are of the pin type and the wires are spaced on 6 ft. centres, six conductors per tower. The damage to the municipal system was such as to take twenty-three hours to repair it and place it in service.

Col. Mitchell Gets the D.S.O.

Hearty congratulations to Lieut. Col. Chas. H. Mitchell, who has been honored by a D.S.O. in recognition of distinguished and valued service as a General Staff officer in the First Canadian Division, and later, when he was promoted to the General Staff of the Canadian Corps, which includes all the several divisions now in France. Col.

Lt. Col. Charles H. Mitchell, D.S.O.

Mitchell's friends will appreciate that, inasmuch as the nature of his duties does not provide scope for spectacular work, this honor has been all the more difficult to obtain, and can only have resulted from the intense application of his well-recognized ability.

New Books

Reinforced Concrete Construction, Vol. II., Bridges and Culverts—prepared in the Extension Division of the University of Wisconsin by George A. Hool, S.B., Assistant Professor of Structural Engineering, and Frank C. Thiessen, B.S., Instructor in Structural Engineering, University of Wisconsin, with chapters and articles by other well-known writers. McGraw-Hill Book Company, Inc., New York, publishers; price $5 net. This volume, on Reinforced Concrete Construction, is devoted entirely to bridges and culverts, and will be followed by Vol. IV., containing a treatment of the remaining structures not already considered in Vols. I., II. and III. The present volume is an attempt to meet the needs of engineers in actual practice throughout the country. Intricate mathematical analyses have been avoided, but the work includes complete methods of design of both symmetrical and unsymmetrical arches, not only of single span, but of multiple spans with elastic piers. Two entirely different methods of arch analysis are presented in order that a check may be had on all arch computations. 682 pages, splendidly illustrated with 575 figures; stiff cloth covers; size of page 6 by 9 inches.

Trade Inquiries

1281. **Forgings.**—A Rugby firm would like to hear from manufacturers in a position to supply large forgings to specification.

1282. **Axles and tires.**—A Nottingham firm inquires for makers of wagon tires and axles to British clearing house specification.

1283. **Forgings.**—A Birmingham firm inquires for best quality forgings.

1284. **Springs and deals.**—A Rotherham firm inquires for railway wagon springs and deals for wagon building 7 by 2½ inches, 7 by 3 inches, 9 by 3 inches and 11 by 3 inches; also oak planks 12 by 5 inches in lengths from 15 feet to 17 feet 6 inches.

Personal

Mr. James L. Morris, C. E., has been appointed engineer for the township of Pembroke, Ont.

Mr. James J. Martindale, whose name has been so closely associated with Tuec Stationary Vacuum Cleaners in Ontario, is returning to the United States. The agency for Ontario has been purchased by Mr. C. B. Owens, who will carry the Tuec line of cleaners in addition to his present line of Powers temperature regulators.

The town council of Barrie, Ont., have appointed Mr. J. S. Laing engineer-assessor. Mr. Laing is a graduate of the University of Toronto in civil engineering. For the last two years he has been assistant engineer of the city of Galt and town of Preston, as well as engineer on the Galt, Preston and Hespeler electric railway. His experience thus covers many classes of engineering work.

Lieut.-Col. Davis, commanding the Second Pioneer Battalion, now in England, is seriously ill in the hospital at Winchester Camp with concussion of the brain, the result of his horse throwing him against a stone wall. Lieut.-Col. Davis is a former city engineer of Woodstock. He was in British Columbia when he offered to form a pioneer battalion, which he recruited partly in the Canadian West and partly in Ontario. He left for England shortly before Christmas.

Obituary

Mr. E. B. Jones, former city engineer of Chatham, Ont., died recently at Erie, Pa.

The death occurred very suddenly on January 16th of Mr. Thomas E. Baker, a popular citizen and prominent contractor of Prince Albert, Sask.

Mr. Peter Hunter, one of the builders to help in the erection of the first G. T. R. station at Montreal, a resident of Guelph for about forty years, and of Toronto for about twenty-two years, died on January 20th at the age of 91. He was born at Rawburn, Berwickshire, Scotland, in 1824, and came to Canada in 1848.

The death is announced of Mr. James Perry Sharp, of Briefond Moseley, Birmingham, England. Mr. Sharp was for many years the junior member of the firm of T. C. & J. P. Sharp, architects and surveyors, St. John, N. B. He afterwards removed to England, where he spent the remainder of his life. He was in his 73rd year.

Mr. G. Colin Carman, a civil engineer, of Cornwall, Ont., and one of its oldest and most highly respected residents, died on January 21, at the age of 79. The late Mr. Carman was engaged with the Canadian Pacific Railway in British Columbia when that road was being built. Later he was engaged on the engineering staff of the Cornwall canal, retiring about fifteen years ago.

Mr. John A. Wheaton, a veteran railway contractor, died suddenly on January 21st, at the age of 78. Mr. Wheaton was born at Wheaton Settlement, Westmoreland County, and in his early life started railway construction work. During his career he built the northern section of the I. C. R., the Inverness & Richmond Railway, Cape Breton; the Albert Railway; N. B. & P. E. I.; Cape Travers branch in Prince Edward Island; the Petitcodiac & Havelock; Moncton & Buctouche; the Central, from Norton to Chipman; also a portion of the Bangor & Aroostook. He retired from active life only a few years ago. For the last seventeen or eighteen years he had resided in St. John, N. B.

Mr. Hogarth Appointed Chief Engineer of Highways

Mr. George Hogarth, of the engineering staff of the Department of Public Works, Ontario, has been appointed Chief Engineer of Highways, succeeding Mr. W. A. McLean, who steps up to be Deputy Minister of the newly-

Mr. George Hogarth, O. L. S., Assoc. Mem. C. S. C. E.

formed Highways Department. Mr. Hogarth holds the degree of O. L. S. He is also an associate member of the Canadian Society of Civil Engineers, and is well known and highly thought of in engineering circles.

Mainly Constructional

East and West—From Coast to Coast

The city of Quebec has issued seventeen building permits of a value of $56,925 since the first of the year.

The Waterworks Department of the town of Barrie Ont., shows a surplus of $3,000 for the year just past.

According to the Halifax Morning Chronicle, building permits in Nova Scotia have increased substantially of late

The Ontario Good Roads Convention will be held in the York County Municipal Hall from the 22nd to the 24th of February.

Canada Nitro Products, Limited, is the name of a new Toronto concern organized with a capital stock of five million dollars.

Poole & Emery, Limited, contractors, Regina, Sask., are applying to change their style to Poole Construction Company, Limited.

About 300 reinforced concrete piles for use as the substructure of the Canadian Northern Railway wall across False Creek are being made by Creelman & Company, Vancouver. When enough piles are in hand work will be started on driving them in as foundations.

The Robert Simpson Company, Limited, will erect an eleven-storey building on Mutual Street, Toronto, to be used for the mail order branch of their business. The building will have a frontage of 279 feet and a depth of 115 feet, and will be 155 feet high. It will be absolutely fireproof, the floors being constructed of concrete and the main walls of reinforced concrete. The reported cost is about $500,000.

Anticipating that the opening of the new Royal Connaught Hotel will increase transient automobile traffic in Hamilton, and that Main Street will be the main thoroughfare for motors, several enterprising citizens are figuring on the construction of big garages and repair shops on that street, according to information handed out by Controller Cooper. It is hoped that the building trades will boom again in the spring.

Important harbor work is to be undertaken by the Public Works Department of Victoria, B. C., during the ensuing year. According to plans outlined by Mr. A. F. Mitchell, acting district engineer, at the annual meeting of the Victoria Inner Harbor Association, the Dominion Government propose during the present year to proceed with the dredging of the northwest passage, north of Pelly Island, between Songhees Point and Work Point, to provide a channel 300 feet wide, and with an average depth of twenty feet at low water.

The new Civic Improvement League of Canada was formally brought into existence at Ottawa on January 20th at a conference which opened in the Railway Committee Room of the House of Commons. His Royal Highness the Duke of Connaught opened the conference, and about 150 delegates from various parts of Canada were present. Mr Thomas Adams, the town planning expert, outlined the objects of the League—namely, the advancement of general civic improvement, the bettering of local forms of government, the drawing of town planning schemes, the re-planning of old districts on modern lines, the improvement of housing conditions in cities, the making and preservation of parks and open spaces in cities, etc., etc.

The case of the Russell Shale Brick Company against Henry J. Tharle, one of the contractors in the construction of the Ottawa Customs House, has been decided by Mr Justice Sutherland, the Russell Shale Brick Company receiving $7,000. The action arose out of an agreement to take brick from the company, which was not carried out. Ten of the fifty-four caissons to be sunk are now in place at the site of the new government piers at Victoria, B. C. It will be more than a year before this project nears completion. During 1915 the following work was done in connection with the contract: All earth and rock excavation has been practically completed. The amount of rubble dumped for the pier foundations is placed at 147,000 tons. Two thousand cubic yards of broken stone used for levelling off the foundations for the reception of the cribs has been deposited. Nine cribs were sunk into position during 1915. The "fill" for these cribs amounted to 13,000 cubic yards, and the "back fill," 82,000 cubic yards. In the construction of the nine cribs 11,000 cubic yards of concrete and 800 tons of steel were used.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Brooke Township, Ont.
Tenders will be received until 2 p. m., February 12th for extensions and repairs to the Parker Lucas and 15th Concession Drains for the Township Council. Plans and specifications at office of Commissioner W. J. Johnston, N. E. Quarter 10, Concession 10, Brooke.

Carleton County, Ont.
The County Council have decided to spend $60,000 on the construction of macadam roads. Clerk, Charles McNab, Nicholas Street, Ottawa.

Colchester South Township, Ont.
The Township Council will purchase a quantity of tile in the spring. Clerk, J. H. Madill, Harrow, Ont.

Dartmouth, N. S.
The Town Council contemplate the construction of water and sewer extensions on Upper Water and Mott Streets at an approximate cost of $3,000. Clerk, Alfred Elliott.

Egremont Township, Ont.
The Township Council will require a quantity of tile for drainage purposes this year. Clerk, David Allen, Holsein.

London. Ont.
The Board of Control are considering the installation of hydrants at an estimated cost of $5,000.

The City Clerk, S. Baker, will receive tenders until February 4th for the construction of about 3,900 feet of 15 and 12-inch sewer. Engineer, H. A. Brazier.

Niagara-on-the-Lake, Ont.
The Town Council are considering the construction of an 8-inch tile sewer on Prideaux Street. Engineer, James Brown.

Port Dover, Ont.
A report has been submitted to the Town Council by James Louden & Hertzberg, 79 Adelaide Street E., Toronto, dealing with two possible systems for water supply, estimated to cost $46,000 and $49,000. Clerk, James Sloan.

Ridgetown, Ont.
The Utilities Board of the Town Council are considering the extension of the waterworks system. Chairman, R. W. Stokes.

Sackville, N. B.
The Town Council intend to secure legislation to enable them to borrow $20,000 for paving on Lorne and Bridge Streets. Clerk, Thomas Murray.

St. John County, N. B.
The County Council contemplate the issue of bonds to the extent of $15,000 for paving. Secretary, J. King Kelly, Prince William Street, St. John.

Tecumseh, Ont.
The Ean Claire Water Works Company Ltd., intend to construct a waterworks system at an approximate cost of $20,000. About two miles of main will be laid.

Zurich, Ont.
The Town Council propose to complete the waterworks construction started last year. Clerk, F. Hess.

Railroads, and Bridges Wharves

North Dorchester, Ont.
The Township Council propose to build three bridges at an early date. Clerk, W. B. Lane, Dorchester, Ont.

Renfrew, Ont.
The Town Council contemplate the construction of a reserve dam at Golden Lake and have applied for the necessary permission. Engineer. J. R. Stewart.

St. Mary's, N. B.
Tenders on the construction of a steel bridge over the Nashwaak River will be received until February 23rd by the Hon. John Morissey, Minister of Public Works, Fredericton. Plans at the Department of Public Works.

Vancouver, B. C.
Plans have been filed with the Registrar for a wharf to be built in front of lot 892, Howe Sound, Westminster District, for the Britannia Mining & Smelting Company, Ltd.

Public Buildings, Churches and Schools

Birchcliffe. Ont.
In connection with the school now in course of erection for the Trustees of School Section No. 15, Scarboro, the contract for heating and plumbing has been let to T. A. Kent, Birchcliffe.

The Congregation of St. Nicholas Anglican Church intend to build a new edifice to replace that recently destroyed by fire. The architect will be appointed in the spring. Pastor, Rev. C. E. Luce.

Estevan, Sask.
Work is expected to start in the spring on the construction of a basement and chancel for the congregation of St. Mathews. Plans are now being prepared by J. Turner. Secretary, W. L. Thompson.

London, Ont.
The interior of the Salvation Army hall will be remodelled in the spring. Particulars from Ensign Martin.

The Department of Militia are considering the conversion of the hospital into a Home for Invalided Soldiers. Particulars from Colonel Shanon, London. Estimated cost, $5,000.

London Township, Ont.
The Trustees of School Section No. 23 propose to erect an addition to the school in the spring. Estimated cost, $3,000. Clerk, Mary Grant, 110 Dundas Street, Ont.

Otttawa, Ont.
The City Council have decided to have plans prepared for sun parlors. Architect not yet chosen.

Portage La Prairie, Man.
Plans and estimates are now being prepared for a two-storey, twelve-roomed school to be erected for the Public School Board. Work will start in the spring. Architect, Frank R. Evans, 130 Selkirk Avenue, Winnipeg.

Saskatoon, Sask.
Negotiations are now being carried on between the City Council and the Salvation Army with regard to the erection of an Industrial Home for Women. Headquarters of the Army, Toronto.

St. John County, N. B.
The County Council are considering plans for balconies at the County Hospital. Work will probably start shortly Estimated cost. $4,000. Architect, E. Neil. Brodie, 42 Princess Street, St. John.

Trenton, Ont.
The School Board are considering the erection of a High School and are obtaining options on a site. Chairman, S. J. Young, Dundas Street.

West Garafraxa Township, Ont.
The Trustees of School Sections Nos. 4 and 10 are considering the erection of schools. Secretaries. W. J. Philip, R. R. No. 3, Arthur, and J. A. Spence, R. R. No. 3, Arthur.

West Peace River, Alta.
The Trustees of School District No. 3,300 have been empowered to borrow $3,000 for the erection and equipment of a school. Secretary, Nelson Pinder, West Peace River.

CONTRACTS AWARDED

Drumbo, Ont.
The contract for plastering and plumbing in connection with the Presbyterian Church has been awarded to Charles H. Beckman.

Montreal, Que.
In connecton with the church basement which is now built on Rosemount Street for the Trustees of St. John Berchmans, 2619 Cartier Street, the contract for cut stone has been awarded to Alderic Cousineau, 2455 St. Urbain Street.

Business Buildings and Industrial Plants

Caledon, Ont.
A. McLeod contemplates the construction of a bank barn. Work will probably start shortly.

Chatham, Ont.
Work is progressing on the erection of a refinery on River Road for the Dominion Sugar Company, Wallaceburg, Ont. Engineer, John A. Shepherd. Approximate cost, $1,000,000.

Conroy, Ont.
E. Collins, Ailsa Craig, is considering the construction of new foundaions under his barns and other improvements.

Cottam, Ont.
The Imperial Bank propose to establish a branch. Manager, W. A. Clark, Essex.

Dundas, Ont.
Plans are being prepared by Martin E. Hewitt for an office and showroom building to be erected on King Street for the Public Utilities Commission. Brick construction. Estimated cost, $4,500. Chairman, R. W. Karch.

Specifications at the Department.

CONTRACTS AWARDED

Niagara Falls, Ont.
The City Council have awarded the contract for supply of cast iron pipe to Gartshore-Thomson Pipe & Foundry Company, Stuart Street, Hamilton. Contract for valves and brass work will be let later.

Construction of Largest Drydock Will Require Use of Varied Plant

The new South Boston drydock is to be the largest in the country, being 1200 ft. by 149 ft. in over-all dimensions. A wide variety of plant, including cableways, locomotive cranes, compressor plant for drills, mixing plants, a variety of floating plant, and, indeed, about everything but steam shovels, will be used by the Holbrook, Cabot & Rollins Corporation in carrying out the contract.

A dredge is already at work on the site of the dock proper, and Morris & Cummins, of New York, who have this part of the work or a sub-contract, are expected to bring up one of the biggest dredges on the Atlantic coast which can handle 150,000 cu. yds. of material per month, and which will make short work of the 450,000 cu. yds. to be dredged from the dock site proper and dumped at sea.

Two large areas of land, between which lies the site of the dock and approach channel, have already been made by filling in between recently constructed bulkheads. The balance of this fill will be made, after the dock is finished, from the material dredged out of the approach channel. This material will also be used to complete the fill between the bulkheads and the dock walls, after a heavy bank riprap to be excavated from the dock floor has been placed around the outside of the walls.

About 85,000 cu. yds. of rock must be excavated all over the dock floor. Considerable saving has been effected in the design by the plan of excavating beneath the walls only enough to secure a solid foundation, a sloping blanket of concrete joining the toe of each wall to the floor concrete of the dock.

The Directors of the Port of Boston designed the dock and will supervise its construction. Edward F. McSweeney is chairman and Roert E. Barrett chief engineer. DeWitt C. Webb, civil engineer, U. S. N., has been detailed by the Navy Department at the request of the Boston board to assist in the design and supervision of the work.

The contractors will spend the time until the dock site is dredged assembling plant. Then a cofferdam will be thrown across the lower end of the site as indicated, and the water pumped out. Active work on removing the rock will not start before the middle of next spring. The work is under the direction of Mr. Rollins, of the contracting firm, but the name of the man who will have direct charge of the construction has not yet been given out.

Tenders and For Sale Department

TENDER
Annual City Supplies

Sealed tenders will be received by the undersigned, addressed to Chester S. Walters, Esq., Mayor, chairman Board of Control, City Hall, Hamilton, Ont., up to five o'clock p.m. on **Wednesday, March 1st, 1916**, for supplying the Corporation of the City of Hamilton with the following:-

Cement; Broken Stone and Screenings; Limestone Dust; Asphalt; Asphalt Sand; Sand and Gravel; Vitrified Brick; Creosoted Wooden Blocks; Lumber; Sewer Pipe; Sewer Brick; Lime; Castings (Ordinary and Special); Iron Pipe; Hydrants; Valves; Extension Boxes; Lead Pipe; Pig Lead; Rubber Hose; Rubber Boots; Road Oil; Lubricating Oil; Flux; Fuel Oil; Coal Oil; Gasoline; Concrete and Garbage Duck Covers; Bass Brooms; Sectional Sweepers; Brass Work, including ordinary and special brass castings for Water Department; Hardware.

Tenders to be on forms supplied, and plainly marked on the outside "Tender for Cement," or as the case may be.

Specifications and form of tender for all of the above can be obtained at the office of the City Engineer, Hamilton, Ont.

A marked cheque for 10 per cent. of the amount of tender (unless otherwise stated in specifications), payable to W. R. Leckie, City Treasurer, must accompany each tender, which will be forfeited should the tenderer and his sureties fail to execute contract within four days after notice of acceptance by the City.

The lowest or any tender not necessarily accepted.

S. H. KENT,
City Clerk.

Hamilton, January 28th, 1916. 5

Separate sealed tenders, addressed to the undersigned, will be received at this office until 4 p.m., on **Tuesday, February 15, 1916**, for the supply of: "Brooms and Brushes," "Chain," "Coal," "Hardware," "Hose," "Oils and Greases," "Packing," "Paint and Paint Oils," "Manilla Rope," "Wire Rope" and "Steam Pipe, Valves and Fittings," for the requirements of the Departmental Dredging Plant in Ontario and Quebec during the fiscal year 1916-1917.

Each tender must be sent in a separate envelope and endorsed: "Tender for Hardware, Ontario and Quebec," "Tender for Chain, Ontario and Quebec," etc., etc., as the case may be.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures. These forms can be obtained at the Department of Public Works, Ottawa.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, for amount stated in form of tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the contract. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, January 21, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—90556. 4-5

Tenders Wanted

Sealed tenders for all trades, with the exception of structural steel, in connection with the erection of the New Princess Theatre, Toronto, will be received until 5 p.m., **Saturday, February 12, 1916**, at the office of the undersigned.

Structural steel tenders will close at 5 p.m., Saturday, February 5, 1916.

Tenders to be submitted on forms to be supplied.

Plans and specifications may be seen at the office of Charles J. Read, Rooms 203-4 Confederation Life Building, Toronto, Ont.

C. HOWARD CRANE, Architect,
CHARLES J. READ, Associate Architect.
4-5-6

Sealed tenders addressed to the undersigned, and endorsed "Tender for Lock Gates at East River Lock, N.S.," will be received at this office until 4 p.m., on **Monday, February 28, 1916**, for the construction of Timber Lock Gates and their equipment for the East River Lock, near New Glasgow, Pictou County, N.S.

Plans and forms of contract can be seen and specification and forms of tender obtained at this Department, and at the offices of the District Engineers at Antigonish, N.S.; Halifax, N.S.; Shaughnessy Building, Montreal, P.Q.; Confederation Life Building, Toronto, Ont., and on application to the Postmaster at New Glasgow, N.S.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

NOTE.—Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of $20.00, made payable to the order of the Honourable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, January 27, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—91583. 5-6

Give the Engineer Authority

"The proof showed that some of the employees under the engineers of the city had no competency whatever. They were **appointed without the sanction or knowledge of the engineers,** who had **no authority** to dismiss them or **to deal with them in any way** at all."

The above statement is made by Mr. Justice Croquet in a judgment just handed down in Montreal, in which it had been shown that the city had lost $80,000 on one single sewer contract as a result of incompetence and inadequate inspection due to lack of authority of the head of this department to remedy these matters. It was further shown that the chief engineer had tried to rid his department of one especially undesirable inspector, but that the latter was reinstated by council. Being dismissed a second time, this inspector then procured a letter from the Mayor of Montreal "ordering" his re-reinstatement.

Yet, in the face of these circumstances, Justice Croquet comments, "when anything goes wrong the chief engineer is the first man who is sought out and held responsible."

And how many of our municipalities could honestly throw stones at Montreal? Isn't this just typical of conditions in numberless cities and towns all over the Dominion? Aren't our engineers continually subjected to the petty authority of temporary elective officials who secure their brief hold on office, nine times out of ten, through "influence" of one kind or another? Don't we every day watch the humiliating spectacle of the trained, competent and efficient man subjected to the whims and made the tool, of some miserable party grafter? To the man who appreciates fair play and honest dealing it is a sickening sight to see our national honor so often apparently made subsidiary to the expediency of rascals, to see dishonesty overrule honesty, incompetence dominate competence, and ignorance browbeat knowledge.

There is no shadow of doubt that infinitely more of our municipal undertakings fail through interference of councils, mayors, etc., than through any fault of the engineers in charge of construction or operation. This fact is not sufficiently well known to the average citizen, however. He is so saturated with the conviction, the product no doubt of his political experience, that all men of that type are grafters, that he does not recognize in the engineer a different class of individual. Why is this? Largely because honesty and ability and modesty go together. The engineer is not an advertiser. He is not a public-spirited man in the usual sense—perhaps not public-spirited enough. His work and studies absorb his whole time. Politics, like golf, is, he believes, a game for the leisurely classes.

The latest statement of Dominion finances, covering the period from April 1, 1915, to February 1, 1916, shows an increase in revenue from all sources of approximately $30,000,000 as compared with the same period a year ago. Also, expenditures have been reduced by $18,500,000. Our revenue position for 10 months is therefore improved to the extent of $48,500,000 as compared with the same period of 1915, or at the rate of $58,200,000 a year.

We believe this has got to change. The engineer must assert himself. His ability, his knowledge, his experience, his training in making impartial judgments, must be advertised. He must do it himself, too, even as others, without these same wares in stock, nevertheless advertise them just the same. The world values a man, after all, largely at his own estimate—must do so until at least they have a chance to form their own judgments—and therefore it appears to be the plain duty of the engineer to be more self-confident, more assertive, more aggressive, more insistent of his ability to do well what others, badly equipped, are doing badly.

When this European war is over a bigger one will begin—it will be a **war of efficiency**. From the lowest ranks to the highest office in this new army there will be no place for the incompetent, or—we lose. Is our system of government—municipal, provincial, Dominion—as at present constituted, likely to make Canada a factor in such a war?

Montreal Good Roads Congress

As already announced in an earlier issue of the Contract Record, the third Canadian and International Good Roads Congress will be held at Sohmer Park Montreal, from Monday, March 6, until Friday, March 10. The decision to hold the congress in war time was reached by the committee on two grounds—first, that the provincial governments are continuing their good roads policy, and that therefore the interchange of views on roadmaking should not be interrupted; and, second, because of the slogan of the Association, which is "Good roads are a national asset, and form part of the defence works of a nation." The aims and objects of the congress are to interest the people at large in the principle of good roads, and to disseminate knowledge regarding the best methods of securing them. To this end the programme of the congress will year by year become less general and more specific, so that, instead of vaguely advocating the merits of good roads, the addresses will be chiefly by speakers particularly qualified to discuss the various aspects of roadmaking—finance, legislation, traffic, location, drainage, foundations, wearing surfaces, binders, maintenance, equipmet, municipal improvements, bridges, culverts, and so on. Some thirty thousand invitations are being sent out, and plans are being prepared to accommodate at least two thousand delegates from various points in Canada. Sohmer Park is one of the largest and most commodious buildings in the city of Montreal. The ground floor of 25,000 square feet will be given over to the Good Roads Exhibition being held in connection with the congress, where practically everything involved in the making of roads will be on display. A large convention hall upstairs will provide ample space for the business and educational sessions of the congress. Further information may be obtained from Mr. George A. McNamee, secretary-treasurer, Dominion Good Roads Association, Montreal.

Canadian Waterpower Researches

"Substantial progress has been made by the various organizations of the Dominion and Provincial Governments in investigating the water resources of the Dominion. The only province that is not now provided with some form of water resources investigation is New Brunswick, but negotiations, now under way, will probably lead to some satisfactory arrangement in the near future. Manitoba, Saskatchewan, Alberta and British Columbia have permanent systematic hydrographic organizations under the direction of the Minister of the Interior. Ontario is gradually being covered by the hydraulic division of the Ontario Hydro-Electric Power Commission. Quebec is being looked after by the Quebec Streams Commission and the chief engineer of Hydraulic Forces. In Nova Scotia there is a co-operative agreement between the Dominion Water Power Branch of the Department of the Interior and the Nova Scotia Water Power Commission. The field investigations of these organizations are being published in a very satisfactory form, although there has been some delay in publishing the data promptly, following the completion of the calendar or water year, as the case may be. The chief engineers of the above organizations have had several informal conferences with a view to co-ordinating, systematizing and standardizing their work, and also to facilitate the publication of the data in a uniform way and promptly. The net result of these informal discussions will be that in the near future, Canada will be completely covered by efficient and effective organizations charged with the responsibility for investigating, in the most complete and comprehensive manner consistent with the dictates of economy, the water resources of the Dominion."—M. James White before C. S. C. E., annual meeting.

The Kaministiquia Power Company

For completeness of installation and continuity of service the Kaministiquia Power Company has few equals, in hydro-electric power developing stations in Canada to-day. The plant is situated at Kakabeka Falls, and delivers its entire output to the twin cities of Port Arthur and Fort William. These cities, at the head of Lake Superior, occupy a strategical position in the commerce of Canada, being the transfer point between the east and west. West-bound merchandise is here transferred from boat to rail, or stored for delivery during the winter months, and east-bound grain, forest and mineral, raw products forming the return cargo are transferred from rail to boat. The transfer facilities required to handle this immense traffic must necessarily be the most reliable obtainable. Electricity has been almost totally used; power being obtained from the Kaministiquia Power Company.

After nine years of operation the company shows a record for service continuity that, we believe, is not surpassed by any other plant in Canada. Trouble, inconvenience, or delay from ice, backwater, or water shortage, are unknown, and from all causes the total interruptions to the system have not exceeded twenty minutes in any one year. During the past year this record was reduced to four minutes.

The plant, which is now complete, has a total development of approximately 30,000 h. p. The original installation was commenced in 1905, was enlarged in 1911, and completed in 1915. The details of additions, which consist of a reinforced concrete aqueduct one and a quarter miles long; the installation of butterfly valves as headgates to penstocks, with their control apparatus; erection of a steel penstock, a 12,500 h. p. turbine, and a 9,375 kv.a. generator with the necessary transformers, switching apparatus, etc., are explained in detail elsewhere in this issue.

Plan to Dredge New Inner Harbor Channel at Victoria, B.C.

Plans for a channel that will afford an entirely new passage into the inner harbor at Victoria, B. C., were discussed at the ninth annual meeting of the Victoria Inner Harbor Association, held in that city on January 11. A. F. Mitchell, acting district engineer of the Dominion Government, outlined plans which the government proposes to follow during the present year in opening up a new channel with a width of 300 feet and a low water depth of 20 feet, by improving what is known as the Northwest passage. Borings have been made, it is reported, which show that in dredging for the new channel no rock would be encountered. This condition is expected to greatly reduce the cost of the work, as well as to expedite the construction.

Efficiency in Municipal Engineering

Importance of intensive studies of the organization, cost of operation and efficiency of service in connection with civic undertakings—Give the engineer a freer hand

By R. O. Wynne-Roberts*

WHATEVER might have been the conditions in the past, there can scarcely be any doubt in the minds of public men to-day that the paramount need now is true economy. Engineering, rightly interpreted, consists in the economical utilization of forces and materials of nature for the attainment of specific results. To do more than is prudently necessary is not engineering. For example, a sewerage scheme will entail engineering ability whether the dimensions of the sewer are excessively large or legitimately adequate, but the engineer who had imbibed the spirit which should dominate his profession will aim at an economical solution of the problem which he has to study. Every expense should be justified by results, although it is not always possible to make them tangible at the time.

Suppose an electric lighting scheme is undertaken and the question arises as to whether the boiler and engine room should be built large enough for probable future requirements. To build a house sufficient for the present needs would cost, say, $50,000, but to provide for the next ten years would mean an additional expenditure of, say, $10,000. The engineer might find it easy to persuade the authority that the extra $10,000 should not be spent, although in five years' time it may cost $15,000 to furnish the same additional accommodation. It is reasonable to argue that the present ratepayers should be saddled only with the cost of the works which they actually want. This attitude is commendable so long as it is not pushed too far. The accommodation may be required sooner, and the works will have to be disturbed by building operations. The expenditure of $10,000 at present would at 5 per cent. compound interest amount to about $12,763 in five years' time, whereas the cost of building at the end of that period would be, say, $15,000; consequently as a business proposition it would be more economical to build now and save $2,237.

A Burden on Posterity

On the other hand, there is a temptation to incur liabilities at present and spread the cost over a long period—sometimes longer than the lifetime of the plant. This of course imposes a burden on posterity in the acceptance of which they have had no voice, and, furthermore, they must in some instances continue to pay for some plant or work which has become worn out, obsolete, or is in some other manner of no value to them. Efficiency and equity in such cases are matters of great importance to the civic financiers, as the load should be borne by those who enjoy the service.

The businesses of street pavement construction and maintenance are of great importance, because the quality of a civic administration may in a measure be judged by the condition of the streets and lanes. An average householder desires to maintain a presentable front-walk and doorstep, although the back yard may be somewhat neglected. In a like manner the city authorities generally like to have the streets appear good—sometimes even at the partial abandonment of other civic essentials. The subject of pavements would be sufficient for a series of articles, because efficiency depends upon the selection of the paving materials, the nature of the foundation, traffic, gradient, foothold, durability, facility of repairs, etc. But in general the pavement work should be of the higher quality suitable for specific conditions. Owing to the lack of judgment on the part of some authorities, and to the persuasive ability of agents in inducing the authorities to adopt some form of pavement, the choice of materials has not always been fortunate, and, as a result, the efficiency of the administration has been impugned.

Persuasive Powers of Agents

In certain instances the persuasive powers of agents have more than counterbalanced the advice of the engineers. The selection of the paving materials for different streets should ordinarily depend upon the cost of construction, life, interest and repayment of loan, the cost of repairs and cleansing. The character of the street demands some consideration, for while a high-class sett pavement may have the lowest annual cost, it would be unsuitable for a high-class business quarter or a residential district. Wood pavements have many virtues when the timber is thoroughly creosoted, but, unfortunately, efficiency in this respect is not the rule, which is greatly to be regretted, because Canada is so bountifully supplied with lumber that it would seem to be the natural paving material, whereas at present the bulk of the bituminous compounds used for paving work are imported. When timber is properly selected, efficiently pickled and carefully laid, it makes a good pavement of great durability.

Efficiency does not particularly appertain to new works; it may have a pronounced effect on the rates when considered in its connection with ordinary daily routine work. The average ratepayer is willing to see new works carried on, as it connotes progress and development; but when the time comes for the account to be paid in the form of demand notes for rates and taxes he then looks around for opportunities to economize, and perchance he may discover a place for the pruning knife. After a long personal experience in municipal administration in various capacities, the writer can assert that economy effected by the electoral pruning shears is rarely the most advisable. This does not mean that retrenchment should not be made, but that which may appeal to the public is not necessarily true economy. The search for economy should be made in all directions, so as to get as near one hundred cents' worth of service for a dollar as is possible, run the civic machinery at the lowest practicable cost, and at the same time assure that efficiency is not sacrificed. No municipal business can be operated like a dry goods store, because in the latter case the concern is managed by one mastermind, but in the former, since municipal matters are managed on the democratic principle, there are as many minds as there are ratepayers. But municipal business, notwithstanding this difficulty, can be carried on efficiently if the chief officials are given a free hand, and money can thereby be saved in many ways. Efficiency will

*Consulting Engineer, Toronto.

be secured provided the engineer is always allowed to think out carefully his plan of operation, and—what is still more important—that he is permitted to carry out his ideas without interference. If he succeeds, then he should receive public commendation; if he fails, then there is room for another engineer in his place. But failure will occur in very few instances under such circumstances. The writer on several occasions has been given a free hand to carry out work and, having the confidence of his Council and carrying great responsibilities imposed in this manner, he devoted every effort to retain such confidence, and succeeded, receiving public votes of thanks and something tangible for his service. Furthermore, efficiency was established and appreciable economics were effected. This statement is not put forward as a symptom of egotism, but as an argument for greater confidence in the engineer and the beneficial results which would accrue therefrom.

Ways of Economizing

There are different channels by which economics may be effected. One of them is through the store department. A city needs a large variety of stores, but it may not be in a position to employ a purchasing agent. It can, however, always keep a store and a store-keeper. Stores should be standardized, and a schedule should be prepared giving particulars of the requirements of each kind. Much might be said about standardizing stores, and the advantages of such an arrangement, but it may be stated that very tangible savings have been effected in this manner. One society in Canada has found it possible to save a large percentage on their printing account by changing their methods of placing orders. It is surprising what quantity of stores are required by an average city, and what they cost in the aggregate. It is by virtue of the stores department instituted by Baron Shaughnessy and copied by some American cities that the Canadian Pacific Railway Company are able to keep the annual expenditure of money on materials under effective control. It was pointed out at a recent meeting of the Toronto branch of the Canadian Society of Civil Engineers that Canadian bags of cement ordinarily weighed 87 pounds and American bags 94 pounds. As one cubic foot of cement is usually assumed to weigh from 94 to 100 pounds, and constitutes the basis of concrete mixtures, it is easily seen that if Canadian bags are used then from 7 to 13 pounds of cement (according to the standard adopted) are saved by the contractors. It is important that the stores should be carefully organized and operated, for a badly managed store department might easily nullify efforts to economize.

Efficiency in Operation of Plants

Efficiency in the operation of pumping and lighting plants is an important matter. Most operating engineers contend that they run their plant at least as economically as others do. Such a claim, however, is not very great when the details of the operating costs of different installations are analysed. The writer not long since had occasion to examine the returns from a number of electric lighting plants and it was surprising to note the great difference in the quantity of coal consumed per kilowatt of electricity sold. There are, of course, many conditions which contribute to such varied results, over which the engineer may have but little control. In one instance it was ascertained that the boiler settings were defective; in another, local inferior coal was used under unfavorable conditions. Notwithstanding these facts, it is essential that all points should be thoroughly investigated and properly adjusted if the rate-payers are to receive value for their money. Oil engines are popular for operating water pumps. It frequently occurs that the quantity of oil consumed per million foot-gallons is excessive. Take a case where one million gallons are raised daily to a total height of 200 feet, which is equivalent to 200 million foot-gallons per day, or 73,000 million foot-gallons per annum. The pumps are operated, say, 15 hours per day, or 5,475 hours per annum. The efficiency of the engine will be about 85 per cent., and of a turbine pump about 75 per cent., so the combined efficiency equals 63.75 per cent. The brake horse power will be

$$\frac{200{,}000{,}000 \times 10}{15 \times 60 \times 33{,}000 \times 0.75} = 90 \text{ B. h. p.}$$

The oil consumption is generally guaranteed at two-thirds of a pint per brake horse power hour, and therefore the quantity per year will be

$$\frac{\overset{\text{B.h.p.}}{90} \times \overset{\text{Pints}}{.66} \times \overset{\text{Hours}}{5475}}{8 \text{ pints}} = 41{,}060 \text{ gallons.}$$

But suppose the oil consumption was actually three-quarters of a pint, then the annual quantity used would be

$$\frac{90 \times 0.75 \times 5475}{8} = 46{,}660 \text{ gallons.}$$

an excess of 5,600 gallons, which represents a good sum.

Examine Machinery Periodically

There are many instances where the oil consumption is one pint and over per brake horse power hour. While it would appear that the oil used would be excessive, it may be taken as an indication that in other respects the efficiency was low. It is very desirable that engines should be indicated at frequent intervals and the cylinders and pistons thoroughly overhauled. Pumps should also be periodically examined and maintained in good condition.

Again, the slip in many pumping plants is high. The average slippage of all pumps in service in Chicago in 1911 was estimated at 15 per cent., while in other cities it is much higher. Slippage should not exceed, say, 5 per cent. before steps are taken to rectify the defects. It is palpable that the rate-payers lose heavily by allowing pumps to simply churn ten per cent. or more of the water. Slippage in meters is another serious item of loss, because if the slip is ten per cent. or more, as occurs in certain cities, then the revenue in those cases is that much less than it ought to be.

Returning to the fuel consumption, it was found in one district where the coal was reasonably cheap that the cost of that fuel per million foot-gallons ranged from two to eight cents, while the total cost of pumping ran from 5 to 21.35 cents. Take another power cost; the electrical energy used in one place cost 1¾ cents per million foot-gallons, and in another it amounted to about 20 cents. It is scarcely necessary to state that there is room for greater efficiency in the latter instance.

The question of what power to employ depends upon a few considerations, such as the size of the plant, type of pump installed, period of pumping, cost of fuel or energy, quantity of water and the height to which it has to be raised, and so on.

As another line of investigation, the cost of street lighting might be considered. Almost all cities, especially in North America, are desirous of maintaining their "white ways"—namely, streets which are illuminated brilliantly and artistically because it is thought that they constitute an attraction and an advertisement. It is questionable whether the rate-payers receive an adequate return for such investment. Besides, efficient street lighting involves the question of how to obtain the most light for the least expenditure of money and how all parts of a city are to receive their due share of lighting. Cluster lights are popular and no doubt add to the appearance of an important street, but the cost of lighting by these means is high when considered from the viewpoint of expenditure per foot-candle per square yard of street surface lighted or per any other standard. It is of course reasonable to expect business houses to incur considerable expenditure of money on exterior and interior lighting so as to make their premises attractive—that is a legitimate investment, on which they expect ample returns; which may be another way of interpreting efficiency, and in the case of a city, efficiency from a monetary standpoint should also come first. This does not exclude the proposition of the brilliant lighting of certain streets, but it does impose a duty on the administration of getting that standard of illumination at the most economical cost. This subject has occupied the minds of eminent authorities at Philadelphia, London, Chicago, Calcutta, etc.

Refuse Collection

Refuse collection and disposal is another line of study worthy of close examination. The writer is fully aware of the different conditions in cities, such as compactness of the areas served, distance of haulage, weight of loads, composition of the refuse, whether garbage, ashes and rubbish are separated, and if street cleaning is attended to by the same team.

An analysis of the statistics which are available reveals a great difference in the cost; garbage collection costs from 6 to 27 cents per capita per annum, Winnipeg occupying an average position on the list. Ashes collection cost from 4 cents at Winnipeg to 73 cents at Boston per capita per annum. The problem in this case consists in the arrangement of the routes so that the teams and men are efficiently employed

Allow the Engineer a Free Hand

Enough has been stated to show the importance of intensive studies of the organization, the cost of operations, and the efficiency of service, in connection with civic undertakings. Thrift is inculcated by our statesmen and advocated by all, but it requires a close investigation into the administration of various departments to obtain the maximum of efficiency at the minimum of expenditure.

Inasmuch as the functional importance of efficiency is as a rule a part of the engineer's training, it is manifest that it would be of advantage all round if engineers were allowed greater freedom in the management of the affairs of their municipalities. It would be invidious to refer to the excellent work done in this direction by engineers, but any one who desires information on the point can easily obtain it by studying the engineering journals. The fact that not much is heard of the achievements of engineers in this connection is probably due to their professional attitude. If they were gifted (?) with some of the attributes of politicians we should hear more of their work.

Petitcodiac Bridge, Moncton, N. B.

New steel structure to replace old wooden one—Specially designed to withstand destructive effects of tides and ice floes—Substructure will cost $200,000

By H. Bruce Jefferson

On June 30th, the Provincial Government of New Brunswick let to Messrs. Engineers and Contractors, Limited, Nova Scotia, a contract for the substructure of a new highway bridge across the Petitcodiac River at Moncton, N.B. The present bridge now in use at this site is a wooden Bhurr arch-truss, built in 1871-72. It replaced a former wooden bridge which had been completed in 1867, after being four years under construction, and which was carried out two years later by the Saxby Gale. Several spans of the present bridge were also carried out by a heavy gale in the nineties. The foundations of both these previous bridges were round timber cribwork piers, filled with rubble stone.

The provincial engineer, Mr. A. R. Wetmore, in designing the new structure, determined to make it absolutely permanent, and consequently found it necessary to secure a solid rock foundation for the mid-river piers. These piers were especially designed by the provincial engineer to minimize, so far as possible, the destructive effect upon the substructure by the heavy ice floes and bergs during the winter months, which are moved about with great violence by the strong tides and currents. These tides and currents present some of the principal difficulties in connection with the present work. The rise and fall of the water in the river is about twenty feet at neap tides and thirty feet at spring tides, and on the in-

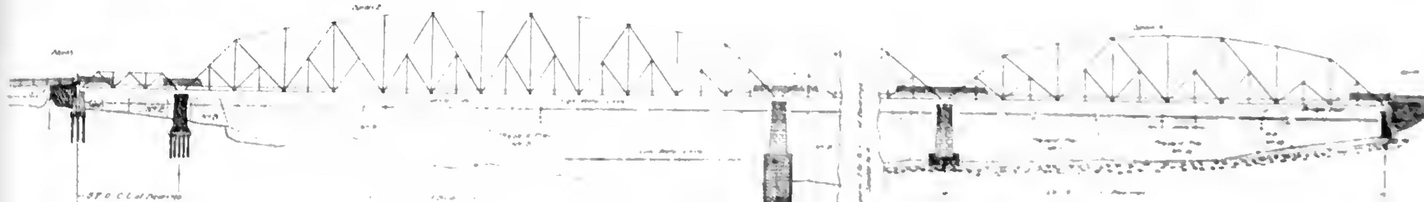

Fig. 1.—Part of side elevation Moncton Bridge showing end span—3 centre spans similar to span A not shown. Total length of bridge 1787 ft. Note relative size of present and new piers.

Fig. 2.—Pier B and north abutment.

coming tide, occurs within a space of about three hours. The tide flows with a velocity of about ten knots per hour, both up and down stream. Another circumstance which adds to the difficulties, from an engineering standpoint, is the regular appearance, twice every twenty-four hours, of the phenomenon known as the "Bore," a species of tidal wave which presents a solid wall of water four to six feet high. This heavy tidal action results in further serious difficulties owing to the fact that the water carries in suspension a large amount of mud which settles thickly upon the work at every low tide.

The accompanying illustrations show the general nature of the ground and the extent of the work required. Pier B (Fig. 2) is situated on the north bank of the river on the Westmorland County shore. The ground was excavated to a depth of about 12 feet, after which sheet-piling was placed and the remaining excavation cleared by means of pumps. It was then piled and capped with a concrete footing course to elevation 58. From elevation 58 to elevation 76, the bridge seat, the pier is of granite with concrete hearting. A similar method of construction was followed with the north abutment (Fig. 2), with the exception that the latter structure is built entirely of concrete. For the south abutment, which has been completed, an excavation was made to solid rock, with sheet piling and pumps, and a footing course of concrete employed as in the case of Pier B, granite being used from elevation 60 to elevation 76. The foundation for Pier No. 4 (Fig. 3), was secured upon solid rock, and a birch grillage laid to elevation 44. From elevation 44 to the bridge seat, 76, the pier is granite with a concrete hearting.

An examination conducted by the contractors, with

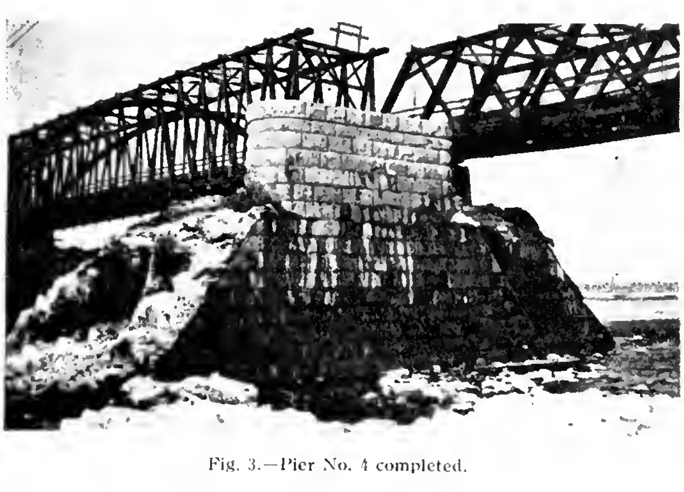

Fig. 3.—Pier No. 4 completed.

the aid of divers and a set of systematic soundings, revealed the situation, at the site of Pier No. 3, to be somewhat different from what was expected as the result of earlier surveys. It had been the original intention to place this pier by the use of the compressed air method, referred to later in the case of Piers Nos. 1 and 2. Through this examination, however, it was discovered that the rock ledge at this point was very uneven and in one place, about the centre of the pier, came to within a few feet of the low water mark. As a result of this discovery, it was decided to make an effort to place the foundation with an open timber caisson, fitted to the clean rock bottom. The contractors built this caisson on the Moncton side of the river, and around it constructed an outer casing allowing a space between, two and a half feet wide, for a puddle chamber. This caisson was launched (Fig. 4), taken across the river, placed in position and ballasted with iron rails to hold it to the bottom. The puddle, consisting of horse manure, clay and other similar material, was then placed in the chamber, and to prevent washing by the out-going and in-coming tides, the top was covered with bags filled with gravel. Pumps were then put to work, and one section was

Fig. 4.—Launching caisson for pier No. 3.

dried and the concrete placed. It was, however, some five or six weeks after the caisson was placed in position before the foundation was finally completed, owing to the fact that, for some unknown reason, the bar below the site of the bridge "made up" and held a greater depth of water than usual at low tide by about three feet. This resulted in such an increase of pressure that, after pumping down a short distance, "blows" repeatedly occurred, letting the water in, and it was only with the greatest difficulty that the foundation was finally secured. It was only possible to work about four hours each tide, which, of course, added to the general difficulty of the situation.

The construction of Piers Nos. 1 and 2 will not be undertaken until the spring of 1916. Recent borings show that a solid rock foundation can be secured for Pier No. 1 at a depth of eighty feet from the bridge seat, or forty feet below low water level. In the case of Pier No. 2, it is expected that the foundation will be secured about ten feet nearer the bridge seat. The contractors propose to secure these foundations by the compressed air method, working only at low tide, thus reducing, as far as possible, the enormous risk of carrying on work of this nature in such swiftly flowing water.

The contract was let by the Provincial Government on June 30th, 1915, and the contractors immediately prepared the ground for the erection of their extensive plant. To facilitate the work, a spur railway line was built from the Intercolonial Railway yards to the northern end of the bridge, a distance of about 2,000 feet, low ground near the yard being approached by a trestle 300 feet in length. At the bridge end another wooden trestle was built upon which cars providing gravel for the company's operations are run and unloaded. All material is conveyed from the north shore to the various structures by a steel cable-way, of Flory design, which consists of a steel cable one and three-quarter inches in diameter, suspended between two towers 1,591 feet apart; the one upon the north bank being ninety feet and the one upon the south bank eighty feet in height. Gravel is loaded from storage into small cars and hauled to the concrete mixers. The cement shed is placed close to gravel storage. A siding has also been built to facilitate the handling of granite, which is unloaded from the cars, upon which it is shipped, by a special derrick car. This car is also used for loading and unloading other materials upon small cars which are run upon a track built, for the purpose, under the cable-way where the material is picked up in slings and carried to the various structures.

The present steam plant, which runs all machinery, excepting steam hoists located near the different piers, for laying granite, other steam hoists, derrick cars and lighters, consists of two locomotive boilers of about 80 h.p., which will be supplemented by the addition of more boilers of about 200 h.p., when the air-compressors are installed. The air-compressors, which are of the Ingersoll-Rand straight-line type, will have a capacity of about 2,350 cubic feet per minute.

E. M. Archibald, of the contracting firm, is the engineer in charge of the work, which is expected to be completed by the first of August, 1916. The contract price for the sub-structure work is $197,000.

Royal Connaught Hotel, Hamilton

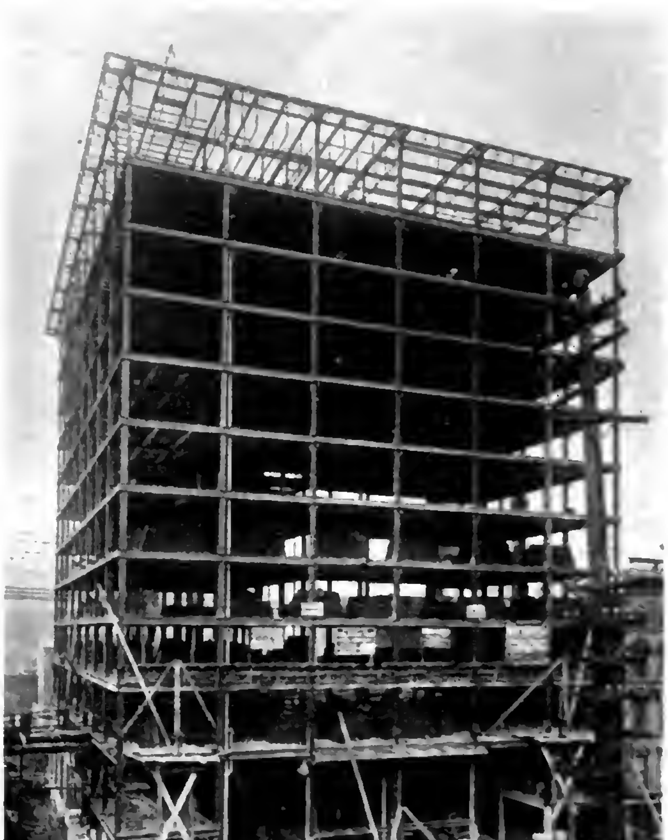
THE Royal Connaught Hotel, now being erected on King Street, Hamilton, Ont., for the Hamilton Hotel Company, Limited, is nearing completion, and will, when completed, be leased and operated by the United Hotels Company.

The building is in two sections; the main building and the annex. The main building consisting of the basement and twelve stories is a steel skeleton supported on reinforced concrete spread footings, with the outside walls or curtain walls built of hollow interlocking tile faced with Bedford limestone up to the second floor level, tapestry brick from the second to the tenth floor, and architectural terra cotta from the tenth floor to the top of the coping on the north and east elevations and with yellow Kittaning brick on the south elevation and in the light court. There is an overhanging terra cotta cornice on the north and east sides, a cast iron marquise over the main entrance, and a Bedford limestone port cochere over the ladies' entrance in the private driveway on the east side.

The floor slabs are four inch cinder concrete, reinforced with triangular mesh wire, designed to carry one hundred and fifty pounds per square foot on the first floor and seventy-five pounds per square foot on all other floors. The roof is a three inch slab to carry fifty pounds per square foot. The floors of the laundry, the public alley over the basement and the roof of the coal room are built of twelve inch hollow tile arches. All ceilings are metal lath except under the hollow tile arches. The partitions are built of three inch and four inch gypsum blocks except around the elevator shafts, where six inch terra cotta blocks are used. All the elevator shafts and stair wells are isolated from the rest of the building by partitions, and the openings in the partitions are protected by fire doors. The outside window frames and sash, in the annex and opening onto the light court of the main building, are metal and glazed with polished plate wire glass. On the east and north elevations the windows are of wood glazed with plain plate. In the upper stories, on the east and north elevation the top sash carry polished plate wire glass.

In the servants' and service portion of the building all the doors and wood trim are pine. In the guest rooms all of the doors and wood trim are birch with mahogany finish except the bath room and closet trim which is pine enameled white. All bath rooms and public toilet rooms have ceramic tile floors and base with cove. The bath room fixtures throughout the building are porcelain.

The main lobby is finished in Mycenian marble wainscot and real marble floor and base. The columns are Mycenian marble with plaster caps. The



Steel frame work erection, Royal Connaught Hotel.

ceiling of the lobby is at the same height as the mezzanine ceiling and deep ornamental plaster beams extend across the ceiling and above the mezzanine gallery. Around the edge of the mezzanine gallery opening onto the lobby below is a wood balustrade, with a wide railing on top. The doors in the lobby are mahogany and the trim is pine to be decorated.

The main dining room has marble floor and base and panelled pine wainscot nine feet high. The ceiling is high with heavy girders covered with ornamental plaster. All of the wood trim is pine for decorating.

All of the wood trim in the restaurant and the bar and grill room is of quartered oak. The floors are marble with a marble base. There is a paneled wainscot in each room and in the restaurant there are four columns. The ceilings are beamed with ornamental plaster.

On the mezzanine gallery and in the large banquet hall on the mezzanine floor the wood trim is pine for decorative purposes. The same applies to the two private dining rooms on this floor. There are eight large wood columns in the banquet hall set close to the wall and tight against wood pilasters of the same design as the columns. The ceiling here is vaulted in five sections separated by heavy plastered beams.

The service equipment includes, besides a complete kitchen layout, a laundry, a refrigerating plant and an auxiliary heating and power plant, including vacuum cleaning apparatus. There are two passenger elevators in the main building and two combined freight and service elevators, one in the main building and one in the annex. The electric service is brought in from outside the building through a switch board located in the basement. The direct current for the elevators is obtained from motor generator sets installed in the basement. There is a private branch telephone exchange at the office in the lobby, connected to each room and to all service departments. There are also six public telephone booths. Telegraph service is available in the lobby. Thorougl ventilation is assured by the installation of a complete system of fans, ducts and registers.

Certain of the difficulties met with in bringing the foundations to grade are here described:

It was necessary to underpin the foundations of the adjoining buildings along the entire west side of our excavation, the depth of the underpinning varying from ten to fifteen feet. On account of the poor condition of the old footings, the work had to be done in sections, filling in alternate spaces after the first piers were carrying their load. On part of the work, concrete was used for the underpinning piers where there was sufficient time to allow proper setting. On the other parts stone piers were built so that the load could be applied as soon as the piers were finished. In one section the underpinning had to be extended several feet deeper because of the change in plans which lowered the column footings at this point. The work was accomplished without the slightest accident to life or property and there has been no settlement of the footings since the underpinning was completed.

Borings were made which showed sand for about 10 feet, then 2 feet of strongly cemented gravel followed by a thick layer of running sand. Below the running sand stiff blue clay was encountered which continued down to the rock. The flow of water and running sand just below the cemented gravel called for heavy sheet piling and constant pumping when building the deeper footings.

Great care was necessary in building the outside basement walls to keep them straight and smooth. All of the outside columns are supported on grillage beams embedded in the concrete walls. This condition necessitated three pourings to reach the top of the wall and each time the forms had to be relined and

Royal Connaught Hotel, Hamilton.

the last section of concrete had to be thoroughly cleaned and coated with cement grout. All footings were poured in freezing weather. Before placing the concrete the bottom of the hole was thoroughly thawed out with steam. All concrete materials were heated and the concrete was placed hot. The completed footings were covered with straw, or in extreme cases were kept heated by steam under canvas. Records have been kept during the construction of the superstructure and at no time has there been any sign of settlement.

The concrete for all of the foundations was mixed in two three quarter yard mixers. It was placed from buggies, the length of wheel averaging about sixty feet.

The building was designed by Esenwein & Johnson, architects, Buffalo, N. Y., with Mr. A. W. Peene as the local associate architect. Stone and Webster Construction Company of Boston, Mass., are the gen-

Refined Asphalt Roads—A discussion of the Merits of Various Materials Used

By Leroy M. Law*

The subject "The Merits of Refined Asphalt Roads" would have scarce been a welcomed assignment five years ago, and in fact, any discussion along such lines would, of necessity, have had to be of prospective nature and of little promise at that, for most service experiences had proven failures, and an inadequate chemistry offered little ground for optimistic productions from the laboratory standpoint. Moreover, prospects, predictions and even promises do not find a very cordial reception in asphalt paving and road building, for municipalities, engineers, and contractors, by reason of their responsibility to others, wisely and justly demand more definite indications to success before changing a type of material or construction.

The "Merits of Refined Asphalt Roads" quite naturally resolves itself into the merits of the asphalts used in their make-up, for in the same type of construction, the mineral aggregates, their preparation, etc., will be practically the same for all asphalts.

The evolution of any product from early types to its more perfected form is dependent upon two factors, raw materials and the processes of manufacture, and in every progressive industry there is constant endeavor to improve both of them. Petroleum doubtless entered the paving industry as a "flux" or softening agency for the solid native bitumen which were too hard to be used for paving purposes in their natural condition. These fluxes were not straight mineral oils, but the residue of by-products of oil distillation. In those days the major products of all refineries were the burning oils, and later on gasoline and lubricants. The fluxes were, therefore, what remained in the still after these more valuable fractions had been taken out, and, under the name of "residuum" were generally considered as containing the lubricating oils, waxes, and pitch base. That they were actually refuse products, with little or no care in regard to their quality, is shown by the fact that the oils were frequently subjected to the so-called cracking processes for an increase over the normal yield of burning oils, but this caused a detriment and injury of the residuum. There are about six oil fluids in the United States, and though the oils in some of them vary from well to well, they are practically all distilled for the same major products. It was not surprising, therefore, that the resulting residues were variable in character, and often unsuited even for the purpose of fluxing the hard asphalts. Under such circumstances, petroleum asphalts originated.

Increasing Use of Native Bitumens

The increasing use of the more successful native bitumens early became the stimulus for the development of the residuals so that they might compete with the asphalts to which they heretofore had served only as adjuncts, and to do so, it was necessary that they be brought from their more or less fluid state to consistencies suitable for paving purposes. It was early found that distillation of the paraffin and semi-asphaltic petroleum beyond the "residuum" stage resulted in decomposition of the pitch or asphalt residues to such extent that their usefulness as paving materials could not be seriously considered, so other means were sought to achieve the desired end. For example, Dubbs found that the addition of sulphur to the residuum, maintained at elevated temperatures, resulted in a molecular condensation with liberation of sulphuretted hydrogen gas. The resulting artificial asphalts received the name of "Pittsburgh Flux."

Byerly, about the same time, found that by blowing air through the heated residuum the oxygen performed a similar function to the sulphur in the Pittsburgh flux and in 1893 took out a patent covering this air blowing process. This proved a most important step in the transition of petroleum asphalt for air blowing was cheaper than sulphur, and by regulating the duration of the "blow," asphalts of varying consistency could be produced. Materials produced by this blowing process have proven useful products, although at no time have they made any serious inroads on the native bitumens, for paving purposes. They were generally tough, rubberlike materials, low in susceptibility, but quite short in character, and have served chiefly as waterproofing, block-filler materials, rubber substitutes, and also to a very considerable extent as a constituent of the bituminous cements in asphalt paving blocks.

Compounding the Residues

Another step in the evolution of asphalts from petroleum was made by compounding with the distillation residues such quantities as hard bitumens, like gilsonite and grahamite so as to produce materials of paving consistencies. Many of these compounds contained as much oil as hard bitumen, and frequently the air-blowing process was used in their manufacture. Several rather successful asphalts of this constitution have appeared on the market in recent years. On account of the large percentage of the oil residuum required, however, the original element of uncertainty still prevails in regard to the finished product. This, together with the high price of gilsonite and grahamite and other factors, has doubtless served to greatly restrict the use of such preparations to-day.

This brings us up to about the year 1900, previous to which the oil asphalts were truly artificial materials, being prepared, at best, from oils of low asphaltic contents and their solidity and consistency were proportional to the artificial means employed in their manufacture. It was only to be expected that they should be called by such names as manufactured asphalts, oil asphalts ,and residual asphalts, even though such designations were not appropriate to the totally different types that followed. Asphalts from Texas and California petroleums next deserve attention, and it is interesting to note that, while they differed widely in characteristics, they are still in use to-day, though in modified form. The original Texas asphalts, on being blown, were low in susceptibility to temperature changes, but the low ductility retarded their adoption by many cities which were maintaining a minimum ductility requirement of 15 or 20 centimeters in their specifications. On the contrary, the California materials possessed practically unlimited ductility, and since they were obtained from full asphaltic base oils, it was

* Before the recent Worcester Convention

possible to omit the blowing process. This fact rendered their advent the turning point in the evolution of petroleum asphalts inasmuch as their preparation could be accomplished by a simple refinement direct to the desired consistency. There has, however, been a lack of uniformity in the crude supplies, and their high rates of susceptibility has been considered objectionable in many places. In spite of this, California materials have been quite successful, and are still in use.

Ideal Raw Material Found in Mexico

The ideal raw material for the production of petroleum asphalts, however, became available about five years ago with the entry of Mexican petroleum into the field of raw materials. These asphalts met successfully, recognized paving and road oil tests, and provided a plentiful and uniform supply of raw material. Mexican asphalts had appeared in the paving industry some years ago, but the early examples were but the more or less solidified effusions from the real supply, which lay thousands of feet below the surface. In 1910 the opening of several large wells on the east coast of Mexico opened a new epoch in the asphalt business. With large supply and reasonable rates of water transportation it was possible to place on the market excellent paving and road building materials at prices which have made possible our great highway developments of to-day.

Two types of Mexican petroleum constitute the general supply of crude material shipped; a heavy oil of 10 to 12 degs. Be. gravity carrying about 70 per cent. of asphalt and a lighter one of 18 to 21 degs. Be. gravity with an asphalt content of 55 to 60 per cent. These are obtained from wells of 3,000 to 5,000 feet depth, are collected in large storage tanks or sometimes in earthen ponds or lakes, and then pumped into specially constructed tank ships ranging from 30,000 to 60,000 barrels capacity, for transportation to the refineries. Both oils yield excellent paving materials. Their high asphalt contents and correspondingly low percentages of light oils allow prompt refinement with a minimum risk of injuring the asphalt residues which, in the handling of Mexican petroleums, are the major products of the refinery. With both types of crude it is commercially practicable to stop the refining or reduction process at any stage of consistency between the fluidity of the natural liquid and the solidity of hardest paving cement so as to give the engineer a material made by one simple process to the desired consistency. By such procedure, the natural fluxes are retained and subsequent artificial fluxing, with its attendant losses in time, is avoided.

Preference for Heavier Oils

For paving cements and road binders there is apparently a preference for products of the heavier oils, probably due to their greater density and lower paraffin content. The lighter oils, however, serve as the chief source for road surfacing materials. When simply freed from moisture and sediment, they serve as a cold surface dressing for macadam roads, the naturally occurring gasoline which they carry serving as a natural thinner to facilitate penetration into the road structure. Deprived of these lighter oils, they serve for the more permanent and so-called hot surface application. That the merits predicted for the materials by scientific tests have been verified is evidenced by their almost general use in many cities for sheet asphalt and asphaltic concrete. In many cities this pavement has successfully passed into its fourth year of service. In road construction and treatments, the uses of Mexican products have been even more general than in street pavements. Such recognition of asphalts from Mexican petroleum show that the early conceptions of "oil asphalts" are fast being obliterated; certainly they indicate that the character of the material itself is to be primarily considered rather than a mere classification in which the material may be placed.

With the entry of California materials, however, the possibility of simplifying the process of preparing petroleum asphalts was noted. This was largely due to the character of the oils themselves, which were fluid asphalts rather than mere oils. A high asphalt content with a corresponding reduction in the amount of burning oils resulted in a complete change of purpose and what had been known as the "residuum" or residue, now became the major product. This is the present practice in the refinement of the Mexican petroleum wherein every possible care is taken to conserve the asphalt constituents, leaving as the refuse or by-products the unnecessary volatile oils which are sold for fuel and gas making purposes.

Radical Change in Petroleum Refinement

This radical change in petroleum refinement has brought forth several new processes, among which may be mentioned those covered by the Dundas and the Trumbull patents. Both are of California origin, the former is little used, but the latter is in successful operation with both California and Mexican oils and is worthy of mention. Its operation depends on preheating the oil, pumping it to the top of heat-jacketed cylindrical towers and allowing it to flow down the inner surface in a thin sheet. Around a central vertical stand-pipe or "off-take" are openings, which allow vapors or light oils to pass off to the condensers. These openings are protected by conical or umbrella-like shields so that they will not become clogged by the asphalt as it passes to the bottom of the tower. The consistency of the asphalt depends on the temperature and the rate of pumping.

The most generally used process, however, is that of steam distillation, which removes the lighter oils from the associated materials at temperatures below their normal boiling points. The petroleum, after the removal of moisture by settling or some similar treatment, is charged into large stills of 1,000 to 1,200 barrels capacity. Heat is slowly applied and maintained throughout the run, but the distillation is actually accomplished by steam vapors. A current of live steam is passed into the heated oil and, issuing from a multitude of fine orifices along the still bottom, carries the light oils with it and the mixed vapors pass to the condensers. While these oils would require temperatures as high as 900 or 1,000 degs. F., for their actual distillation, this steaming process enables them to be removed at temperatures as low as 600 to 650 degs. F., but in proper regulated plants the asphalt in the still is never allowed to exceed such temperatures. Agitation due to the passage of the steam further assists in the work, by preventing any portion of the asphalt being long in contact with the still bottom where the heat is necessarily greatest. In the best regulated plants, recording pyrometers indicate the actual temperatures at all times and when careful tests show that the desired consistency has been reached the charge is allowed to cool and is then pumped into storage or drummed for shipment.

Opposition to New Materials

Following the path of its predecessors, it was, perhaps, to be expected that the higher types of petroleum asphalt as represented by the Mexican products, would encounter suspicion, doubt, and opposition on entering the field of competition. There had been, however, a parallel advance in the science of testing bituminous materials and it was anticipated that this would go far toward assuring reliability. It did to a very large extent; otherwise petroleum asphalts would not have attained their present high standing. Specifications were frequently deliberately closed to these materials, but thanks to the chemist and the engineer, these conditions have been largely eliminated, and the best type of petroleum asphalt are welcomed in open competition with all other good materials.

The Paris Building, Winnipeg, Man.

ON Winnipeg's principal thoroughfare, almost opposite the General Post Office on Portage Avenue, and just South of the junction of Portage Avenue and Main Street, there has been erected a magnificent $200,000 reinforced concrete building which has been named the "Paris Building."

Foundation Work

The general contractors, Carter-Halls-Aldinger, Ltd., have erected a five storey building 88 feet wide by 130 feet deep, but the building is designed for a future ten storey building with a 125 lb. live load on the ground and second floors and 65 lb. live load on the remaining floors.

The average size of column footings is 14 feet square with 30 inch columns in the basement. The system of reinforcing used by the C. A. P. Turner Company, the reinforced concrete engineers for the building, was a two-way beam and slab, the panels being 18 ft. x 22 ft. 6 in. In all there were 3,000 yards of reinforced concrete and 220 tons of reinforcing steel used in the skeleton frame of the building. A 1-2-4 mixture was used for the concrete, sufficient crushed granite being added to the gravel to bring the coarse aggregate up to the correct proportion. All the pits have a 7 in. concrete wall and 5 in. concrete bottoms.

Paris Building, Winnipeg—completed.

The exterior walls on the outside up to the grade line on all sides of the building are waterproofed with half inch coat of cement mortar and pudlo waterproofing compound.

The exterior finish of the building is terra cotta with an interior backing of good hard stock brick. This brick backing is laid simultaneously with and bonded into the terra cotta facing, with anchor rods, ties, etc., while the inner four inches of all exterior walls is laid with hollow brick. All interior walls and partitions are built of 4 inch hollow tile. The brickwork throughout the building is laid up in cement mortar compound as follows: One part best Portland Cement to three parts of clean sharp sand.

It is interesting to note that portions of walls, etc., bearing severe loads are built in extra hard brick, special care being taken that these portions of the work were well pointed, flushed up and grouted. Row lock arches are turned over all arches in brickwork. The walls facing the lane at rear are built of good hard stock brick, which were carefully selected for their evenness of color and face. The brickwork on the light court is of the best quality lime brick.

Electric Installation.

A complete system of wiring for electric lights, fan outlets, etc., has been installed. The wiring is for 110 volts alternating current on the three wire system.

The power wiring is for two passenger elevators with the exhaust fan on the roof at 550 volts direct current. The Star Electric Company, Winnipeg, installed the transformers and extended the mains in conduits to the switchboard which is located in the engine room in the basement. The general contractors, Carter-Halls-Aldinger, Ltd., Winnipeg, connected all the mains to the switchboard as well as extending the switchboard panels, which are of black slate 2 inches thick and 6 feet 6 inches high. The switchboard panels provide for the following fittings: Lighting panels, 110 volt alternating current, on which is mounted the following fuses, switches and meters:

One for each of the small stores facing Garry Street.

One for billiard room in basement.

One for each of the Portage Avenue stores and basements to same.

One for barber shop in basement.

One for all corridor, stairway, lavatories and boiler room, lights.

One for each of two show rooms on the second storey.

One for each office of three office floors above.

One for disc and fan motors in corner store and billiard room in basement.

The power panel, having 500 volt direct current, has the following fuses, switches and meters mounted thereon: One for each elevator motor and one for fan motor.

All fuses installed are of the renewable type, and each panel is completely wired on rear, devices and instruments connected to proper circuits, being ready for instantaneous operation.

The bus bars, which have been installed, are round copper, and are specified not to carry more than 800 Amp. per square inch.

The roof is covered by Barrett's tar and gravel roofing. All the elevator doors are of frame construction, excepting the door to the stair from the main entrance hall which is of hollow pressed steel, manufactured by McFarlane & Douglas, Ottawa. The main staircase from the basement to the roof has wrought iron ornamental railings with channel steel angles to receive the wood hand rail and rests on the moulded metal saddles cast to fit the concrete stair string.

The interior of all brick walls, brick and other partitions, the columns and the inside of all exterior walls, the inside of passenger elevator shaft, etc., throughout the building are plastered by the Western Plaster Company, of Winnipeg, with two coats of Manitoba hard wall plaster and one coat of white hard finish, all of which was supplied by the Manitoba Gypsum Co., Winnipeg.

The floors of the main entrance hall and vestibule are laid in marble square tiles 10 ft. by 10 ft. 1⅛ inches thick.

The walls of the main entrance vestibule and elevator wall up to the height of 4 ft. 6 in. have been laid up with 1 inch marble wainscot. The Missisquoi Marbles Ltd., Montreal, supplied the marble for this building.

The interior finish of the building is selected straight grained white oak, supplied by the G. W. Murray Company, Winnipeg.

The building is heated by a low pressure system of steam heating.

The structure was completed in quick time, the contract being let on April 15 last year to Carter-Halls-Aldinger, Ltd., and the tenants were occupying the new building within seven months of that date. Woodman & Carey were the architects.

Church of St. Francis of Assisi, Toronto

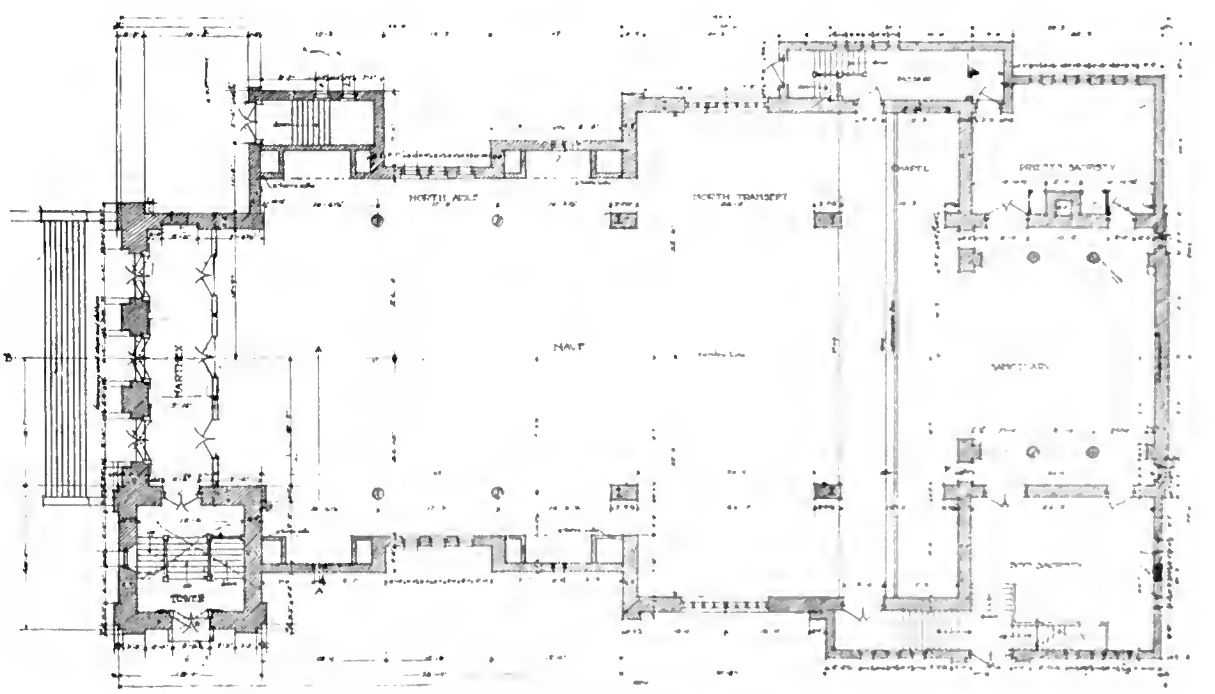
The new Church of St. Francis of Assisi, Grace Street, Toronto, was completed and dedicated in October, 1915. The building is in the Italian Gothic style, and is built chiefly of Credit Valley stone, with Indiana limestone dressings, except the pinnacles, niches, window tracery, etc., which are carried out in Roman stone. All interior columns, with their bases and caps, are built of Indiana limestone.

The main entrance, on the west, fronts on Grace Street, and utilizes three large double doors surmounted by ornamental, artistic windows in Roman stone relief. Access to the building may also be had through two entrances on the north, which are approached by a private walk, and by two more on the south, off Mansfield Avenue. Directly within the main entrance is a narthex 37 ft. 6 ins. by 9 ft. 10 ins., which is also

Church of St. Francis of Assisi, Grace St., Toronto.

Interior of St. Francis Church, Toronto. A. W. Holmes, Architect.

directly accessible through the tower from Mansfield Avenue. Three double swinging doors, corresponding respectively to the main entrance doors, open directly from the narthex, or vestibule, into the main body of the church. Directly over the narthex is the organ gallery. In the southwest corner is a tower 21 feet square, approximately 120 ft. high, with an open arch belfry, beautifully ornamented with Roman stone relief work. The nave in the main body of the church is 40 feet wide, and is flanked by narrow aisles, used

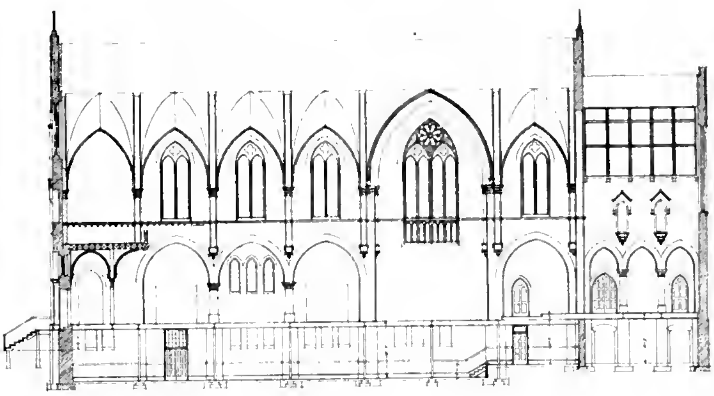


FIRST FLOOR PLAN
First floor plan, St. Francis of Assisi, Toronto.

as passages only, with a main aisle down the centre. On the north side of the sanctuary, which is situated at the east end of the church, is the priest's sacristy, with the boys' sacristy on the south side. The clerestory, which is supported by Indiana limestone columns connected by high arches, contains several large windows on all sides which efficiently light the body of the church. The lower set of panes of all windows on any one side of the church are connected with a link motion so that the windows may be opened by the operator from the floor below.

The roofs are supported by steel trusses, and the vaulted and groined ceilings are formed of steel framework with metal furring and lath. Ceilings and wall surfaces are finished in rough stucco with staff ribs, strings, corbels, and other ornamental works. The roof is slate covered. The basement auditorium, which is used as a parish hall, has a floor plan quite similar to the first floor, and will seat a similar number of people—namely, nine hundred. The east end of the basement is used for boiler and furnace rooms.

Furniture and all interior trim is quarter-cut oak. The church proper is lighted by two large 16-lamp



Sectional Elevation, St. Francis Church.

clusters over the main aisle, two 7-lamp clusters in the transepts, and single drops over the side aisles. Enclosed shades are used throughout. The total cost, including furniture, is nearly $120,000.

The building was designed and the erection superintended by A. W. Holmes, Architect, Toronto. The general contractor was Mr. R. Sheehy, of Peterborough; sub-contractors, heating and plumbing, P. J. Hayes; electric wiring, Bennett & Wright; fixtures, F. C. Henderson; mosaic work, the Italian Mosaic and Marble Company; furniture, the Globe Furniture Company and the Rosenblatt Art Works; steel sash and ventilators, A. B. Ormsby and the Luxfer Prism Co.

A postal-card poll of the Architectural League, Toronto, showed that three-fourths of the members were in favor of admitting women to their ranks. This sentiment will probably be incorporated into the constitution at the next annual meeting of the League. Architects, painters, and sculptors are eligible as members, and from the first, women have shown their work in the League's exhibitions.

Orders have been received in Montreal from Ottawa asking for the immediate recruiting of a detachment of fifty engineers. It is hoped that men who have had university training in applied science, engineering and similar courses will volunteer for the work, as their wider knowledge and training will make them valuable.

Quarantine Against Dry-Rot As Feasible As Against Small-Pox

According to the more recent authorities, decay in wood is a disease that may spread as smallpox spreads among the unvaccinated of the human race. No wood will decay unless the germs of decay are communicated to it from wood or other vegetable substance already infected. Rot is not inherent in wood or in anything else. It is communicated from subject to subject by the spread of the germs from one to another.

Decay in wood is caused by a plant growth that takes root among the fibers of the wood, and develops and spreads. The plant which does this is called a fungus. There are many species, some preferring one kind of wood, some another; some spread rapidly through the cells and fibers, producing rapid decay, others work slowly and do little harm. The germ which furnishes the means of spreading the rot from one piece of wood to another is called a spore. It is not exactly a seed, but it amounts to the same thing. When it falls on a piece of wood where the conditions of moisture and warmth are suitable, it grows like a seed, and sends roots into the wood and dissolves its substance, and that produces decay. The spores which do this are usually too small to be seen separately without a strong glass, but each microscopic speck may become a centre of infection. Spores develop and fly away through the air in countless millions, and fall everywhere in the vicinity, spreading rot over the surface of sound lumber if sufficient moisture is present.

Suggestions have been many times made that decaying lumber should not be shipped, because of the probability that it will communicate its own disease to sound lumber along its journey or at its destination. Without doubt such a thing often happens.

A little care in handling the material in the yard will prevent the incipient stages of decay, which, when transferred to buildings, may develop into full-fledged cases of dry-rot or decay.

The term "infected wood" may be defined to cover wood which contains the roots of any fungi which can continue to grow under the conditions in which the wood is to be used.

The sale or use of infected wood (that which contains fungi which can grow under the conditions of use) should be prohibited by law.

Our building codes require that steel girders and beams in the downtown office buildings be covered with concrete to prevent collapse in case of fire. Why should we not have a similar requirement that timbered structures be erected in such a way that dry-rot infection is impossible, the code to be so worded that ventilation, heat or preservative treatment be provided for under given conditions?

If the timber can be rapidly dried out and kept dry under the conditions of use, dry-rot cannot develop.

When a building is framed the ends of the girders and posts are usually fitted so tight together that drying is exceedingly slow, and it is frequently further retarded by the side plates of the girder supports. This is one of the principal points where dry-rot starts, because all the surfaces of contact have been or are subject to infection. However, the growth of dry-rot can be avoided by constructing these joints so that air can circulate around the heads of the sticks.

Where drying is likely to be slow because of poor ventilation or absence of heat, a wood preservative should be applied to the surfaces of contact.

Constructing Sewers in Winter Time

By Harrison P. Eddy*

UNDER many conditions that work which is most uniformly and continuously performed is most economically done. It follows logically, therefore, that where conditions are equally favorable at all seasons the greatest economy will result in the long run, if construction work is prosecuted at a uniform rate of speed throughout the year. Such a program would avoid waste due to great haste, which is always accompanied by inflated prices of labor and materials; would tend toward lower unit costs of labor and plant, which would then be continuously employed; and would render unnecessary a substantial portion of overhead costs due to idle capital and supervisory services while the work temporarily ceases.

Such is the ideal, a goal which can be kept in sight with advantage, but one scarcely to be attained in the cold climate of Canada and Northern United States. Nevertheless, much can be done to minimize the losses due to suspension of operations, if only resource and ingenuity are actively employed to overcome conflicting conditions.

Must Select the Work

Perhaps one of the most important steps is that of the selection of the work least unfavorably affected by low temperatures and snow. Upon sewerage and drainage works interior repairs are often made more advantageously in winter than in summer, because the air in the sewers is better, temperatures and humidity are lower, and infiltration and storm flows are at a minimum. Tunnelling may often be done advantageously in winter for here, too, atmospheric conditions are more favorable. These two classes of work can probably be done with as great, if not greater economy in winter than in summer.

Trench work is more difficult to do economically in cold weather, but even here, if selection can be exercised, the losses may be much reduced. For instance, deep ledge cuts may often be made with reasonable economy. The rock is no harder in winter than in summer. The same number and depth of holes must be drilled and the same quantity of dynamite must be used. Great care must be exercised to prevent the freezing of dynamite, but this can be done readily and does not entail material expense. On the other hand, a failure to exercise proper care may result in disastrous accidents and substantial resulting expenditures. Steam and air are slightly more expensive in winter, but with simple precautions this loss will be small.

Trenches in earth are likely to be rather costly—less so in dry sand and gravel than in wet silt, clay or hardpan. In travelled streets in New England the ground freezes to a depth of four to six feet. To loosen frozen ground with picks is an exceedingly expensive operation. It generally pays better to soften it by thawing the frost. This may be done by building fires in the street where the trench is to be excavated. One or two laborers can tend fires at night which will thaw sufficient ground for a trench one or two hundred feet long, but this method is better adapted to a depth of frost not exceeding two feet than to greater depths. This method may be subject to objection on the part of residents in the vicinity, on account of real or fancied danger of setting fire to their buildings.

Another method described by the author in "American Sewerage Practice," Volume II, p. 59, is that of steaming out the frost. When a steam boiler is available this method is quite economical and satisfactory. The ground along the location of the proposed trench is covered by wooden boxes open at the bottom. In the top of the box, which may be 12 to 15 ft. long, 10 inches high and the width of the trench, 2 in. holes are bored about 12 in. apart in rows about every 24 in. crosswise of the box. The boxes are banked around with soft earth, to prevent the escape of steam and warm air from within. One man can tend the fire under the boiler and steam out the frozen ground during the night. For steaming he uses a 3/4-in. gas pipe about 6 ft. long, provided with an iron cross-bar for a handle. To the end of this pipe the steam hose is attached, the other end being open. The operator places this pipe in a vertical position on the ground, passing it through one of the holes in the box. As the steam thaws the ground he gradually works the pipe down until he has penetrated the whole layer of frozen ground. He then withdraws the pipe, plugs the hole with a wooden plug and follows the same course in the next hole, and so on until he has thawed the entire length of ground required for the next day's trench. One man will usually be able to thaw out sufficient area of street for a trench four to six feet wide, 48 feet long, in one night, where the frost is 4 ft. deep.

It is usually practicable to place masonry in trenches in rather cold weather without serious extra cost, although materials should generally be heated. It is also desirable to cover the masonry and to provide some artificial heat to hasten the setting of the cement.

Trench Work Most Difficult

The backfilling of the trench and clearing up the street behind the finished sewer, are perhaps the most difficult and unsatisfactory parts of sewer construction in winter. Where practicable, the trench should be excavated and backfilled the same day, to prevent the freezing of the excavated material, especially if it is wet. It may cost more to re-excavate this material for backfilling than it did to excavate the trench in the first place. Filling a trench with frozen earth is to be avoided, if possible, because it is not possible to compact the fill so as to prevent future settlement.

In spite of the exercise of care in selecting the type of work to be done in winter, the use of labor-saving devices and the expeditious handling of the construction, winter work is almost certain to be less economical than that done under the more favorable weather conditions of the remainder of the year. However, under some conditions the additional expenditure may be warranted. Each case must be decided upon its own merits after a careful weighing of the advantages to be gained and the disadvantages certain to accompany winter work in cold climates.

On account of the present prosperous state of the steel trade, the United States Steel Corporation have decided to increase the wages of their unskilled employees by about ten per cent.

---

* Of Metcalf & Eddy, Consulting Engineers, Boston, Mass., U. S. A.

Instructions on Making Concrete for Isolated Builder

The following brief instructions concerning the essentials of good concrete have been prepared by the Association of Portland Cement Manufacturers, having particularly in mind the needs of the farmer or similarly isolated individuals. Failures in concrete sometimes occur on account of lack of knowledge of the fundamental principles but it is believed that if these simple instructions are followed satisfactory results will be assured in all cases.

Aggregates to be Used in Concrete Construction

The sand, stone, and gravel usually found upon the farms of the United States are generally suitable for concrete construction, provided the following precautions are taken:

1. These aggregates must be free from vegetable matter, dirt, or other foreign substances.

2. When using bank-run gravel, the sand must be separated from the stone or pebbles by screening through a ¼-inch screen.

3. In small concrete structures, such as drain tile, fence posts, etc., the coarse aggregates (crushed rock or gravel) should range in size from ½ inch to ¼ inch. For larger work, such as silos, barn floors, ordinary foundations, etc., coarse aggregate should range from 1½ inches to ¼ inch.

4. The sand used should be coarse, hard, and clean, and graded from ¼ inch to fine, with the larger size predominating. Use great care in hand mixing. It is economical to buy a small machine mixed if the farmer intends to use concrete in large quantities.

QUANTITIES OF MATERIAL FOR ONE CUBIC YARD OF RAMMED CONCRETE

(Table from Taylor and Thompson, "Reinforced Concrete.")

Proportions by Parts			Percentage of Voids in Broken Stone or Gravel

* Use 50 per cent. columns for broken stone screened to uniform size.

† Use 45 per cent. columns for average conditions and for broken stone with dust screened out.

‡ Use 40 per cent. columns for gravel or mixed stone and gravel.

Hand Mixing

Proper methods when concrete is mixed by hand, using a two-bag batch of 1:2:4 proportions, are as follows:

1. Size of measuring box for sand should be 2 feet square by 1 foot high, thus containing 4 cubic feet.

2. Load sand in wheelbarrows and wheel onto mixing board.

3. Fill sand-measuring box, lift box, and spread sand 4 inches thick over board.

4. Take two bags of cement, place contents as evenly as possible over sand.

5. Turn the sand and cement over until thoroughly mixed, so that no streaks of cement or sand appear.

6. Spread the mixture of sand and cement out carefully, place measuring box beside it, and fill twice with stone or gravel, then empty onto sand and cement mixture and mix thoroughly.

7. Add three-quarters of required amount of water slowly and evenly, at same time mixing the mass.

8. Continue mixing, adding balance of water when dry spots appear, until whole mass has been turned over three or four times. This should be sufficient. After final turning shovel into compact mass ready for wheeling to place.

Bank-run Gravel

Bank-run gravel is sometimes used as it comes from the bank. This is wrong, as no two places in a bank will have the same proportions of sand and pebbles. It is, therefore, always essential when using bank-run material to screen the sand from the gravel and remix in the proper proportions.

Colour Possibilities of Concrete

One of the strongest objections by architects to the employment of concrete for the external finish of enclosing walls is the unpleasing tint of the material as ordinarily prepared. A good deal of attention has been devoted to the surface treatment of concrete. White Portland cement has been used in many cases, but its cost is rather prohibitive for average work. Coloring matter, mixed with the sand before the addition of cement and water, is employed by various firms engaged in the production of concrete stone. The most satisfactory way, however, of obtaining a pleasing color and texture in concrete surfaces is to select aggregates of appropriate tint, and to clean away the cement so as to expose the stone. A surface so produced will not deteriorate and is exempt from the disadvantages attaching to rendered and to artificially colored surfaces. The film of cement coating the aggregate can be removed by brushing while still green, afterwards treating the work with a weak solution of hydrochloric acid, and washing away all traces of acid. Concrete surfaces may also be tooled in the same way as natural stone, the best results being obtained by mixing the concrete to be so worked with aggregate of small gauge. The material must be thoroughly hard before tooling, otherwise sharp edges and surfaces of fine texture cannot be obtained. By the judicious combination of tooled surfaces and details with surfaces obtained by the exposure of colored aggregates, the architect will be able to secure results of very pleasing character, and which possess the merit of exhibiting the materials actually employed throughout the construction.—Stone Trades Journal.

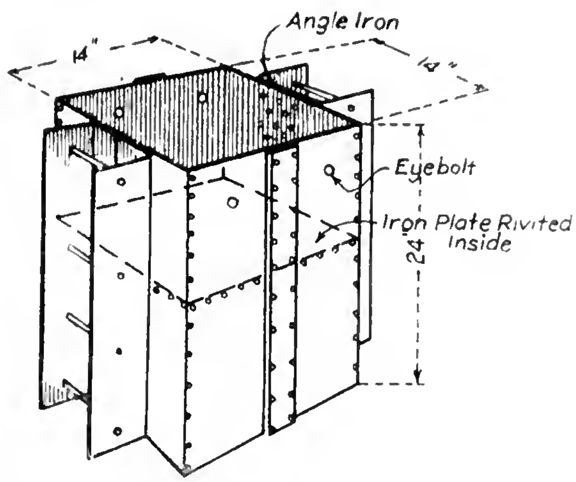
Properties of Manganese Steel

The chief characteristics of manganese steel were summarized in a paper read before the International Engineering Congress, as follows: this steel usually contains 10 to 13 per cent. of manganese and approximately 1 per cent. of carbon. It is practically nonmagnetic and has a peculiar hardness, to which it owes a remarkable resistance to abrasion. It is extremely difficult to machine. It has high strength and toughness, but relatively low elastic limit. With care it can be forged and rolled. It has found its principal application in castings for crushing and grinding machinery and railroad crossings.

Cap Used in Driving Concrete Piles

The accompanying illustration shows a steel driving cap of a type that has been successfully used in driving concrete piles. It is made up of ½-inch steel or iron plates braced with channels or angles on the sides as shown. A plate is riveted in the centre and holds the cushion in place on the pile. The cushion is six inches deep and is made of coils of manila rope. Often old fire hose or felt or belting is used for this purpose. Planks are sometimes placed under the cushion to help in distributing the blow over the top of the pile.

The cushion is placed in position and the iron cap is lowered over the pile to hold it in place. An oak follower is then placed on top of the plate inside the cap. If a steam hammer is used, it is fastened to the caps by means of a wire cable through the eye bolts on the side of the cap. The follower projects above



the top of the cap and is banded at each end to prevent splitting.

In the work where this cap was used, a large breakage was reported when a steam hammer was being used, so a heavy steam hammer was substituted and the ram was allowed to fall the length of the stroke, 3½ feet, without any steam pressure behind it. This method was very successful.

In recent pier work in San Francisco, however, concrete piles 106 feet long were driven with a very small percentage of breakage with a steam hammer.—Cement World.

House Plans at the Building Show

One of the features of the Complete Building Show at the Coliseum, Cleveland, will be in the house plans resulting from a competition for $500 in prizes, which has been offered for the best design for a house to cost $3,000. Special arrangements are being made to visualize the first prize plans in the exposition. The Cleveland Art Association will erect at the Complete Building Show a miniature model of the prize-winning plan and will surround this with the room arrangements in full scale, each room completely decorated and furnished.

The competition is under the direction of the Cleveland Chapter, American Institute of Architects, in co-operation with the Cleveland Art Association, the Cleveland Builders' Exchange and other civic organizations of the city.

Test of Hollow Building Tile

A very interesting test of hollow building tile has been made by the United States Bureau of Standards. A floor slab 6 feet wide and 30 feet long, continued over three piers 15 feet apart, was made of this class of material. This tile is of a special type for use in floor slabs, and is made so that the bottom surface is about 2 inches wider than the top. In laying the tile in the form of a slab, the pieces touch on the bottom, but are about 2 inches apart at the top. This space continues throughout the length of the slab, and is filled with a mortar of the composition of one part of cement and two of sand, in which are placed several reinforcing rods, bent up at the ends of the slab and continued through the concrete beam into the next adjacent slab.

In the present case the two slabs were allowed to age for one month. Tests were made of these, loaded uniformly with pig lead, numerous deflection readings being made as different loads were applied. One of the slabs was able to withstand a slightly greater load, 690 pounds per square foot. Failure occurred in the mortar beams, due largely to the inferior grade of reinforcing used. One of the concrete supporting piers also failed near its base. While the load carried was not up to the expectations of the manufacturers of the tile, yet it was considerably in excess of that demanded by most building laws.

Annual Road Builders' Convention

The thirteenth annual convention of the American Road Builders' Association has been changed a week from the original date, and is now scheduled for the week of February 28, the closing day being March 3. The meeting will be held in Pittsburgh and an interesting program is being worked out.

Roadmaking Equipment Catalogues

The Department of Highways, Ontario, will be pleased to receive current catalogues and literature from manufacturers of and dealers in roadmaking material and equipment. Geo. Hogarth, Chief Engineer of Highways, Parliament Bldgs.

Diesel Installation in Duncan, B. C.

Latest type of this machine operating continuously for many months—High efficiency at all loads—Low rotative speed

By W. Poole Dryer

Particular attention attaches to the new municipal electric power plant at Duncan. It marks a further advance in Diesel engine design and construction. The installation consists of two Morley-Guldner Improved Diesel engines, each of 100 h.p., direct connected to three-phase alternators. Since the plant started operation several months ago, it has carried the entire town load and is giving twenty-four hours' service. It is satisfactory to record that the engines have given continuous service without stoppage, showing that Diesel engine power plant is absolutely reliable and free from mechanical troubles. Engines made to these designs have been installed during the last few years in remote places all over the world; their reliable operation where skilled attention is not obtainable has justified the modifications made to older Diesel practice.

The true Diesel 4 cycle principle is retained. The elevation of efficiency and the elimination of troubles are obtained by boldly adopting low rotative speeds—none of these engines run at more than 212 r.p.m. This twofold result of low speeds is well worth the change, for nothing so retarded the general adoption of Diesels for years as the attempt to make the engines run at high speeds for which they are not inherently suited—most of the mechanical troubles were due solely to that cause. The low speeds slightly increase the size of the engine, but ensure great reliability in operation; lower fuel consumption is a necessary concomitant of low speed.

Valve Mechanism

A radical change is introduced into the valve operating mechanism, as will be observed on the accompanying illustration; the cam shaft is fixed low down on the frames, not as in the older Diesels up among the congestion of valve levers at the top of the cylinders. By lowering the cam shaft to this new position, the valves and levers are left very accessible and can easily be removed—a point all operators will appreciate; and the cam shaft itself is now in a very convenient position, being just at the hand of the operator standing on the floor. A further important innovation is that the cam shaft runs in an enclosed oil bath which ensures perfect lubrication and silent operation—the usual Diesel click of the cam shaft is absent. The vertical rods seen in the illustration are the valve connecting rods which are moved up and down by the cams at their lower ends.

Governing

A separate fuel oil pump is used for each cylinder, thereby ensuring an equal distribution of work between the cylinders. The speed of the engine is regulated and controlled by a spring loaded governor which proportions the amount of fuel oil used in each power stroke to the momentary load of the engine. This is effected by the governor automatically adjusting the opening of the fuel oil suction valve, holding it more or less open as the speed varies, and so allowing the excess oil to be pumped back into the suction pipe instead of being forced to the cylinder.

The governor itself is located on the top of the vertical shaft which drives the cam shaft, and it has a speed-adjusting device attached to it by means of which the speed of the engine can be altered while running.

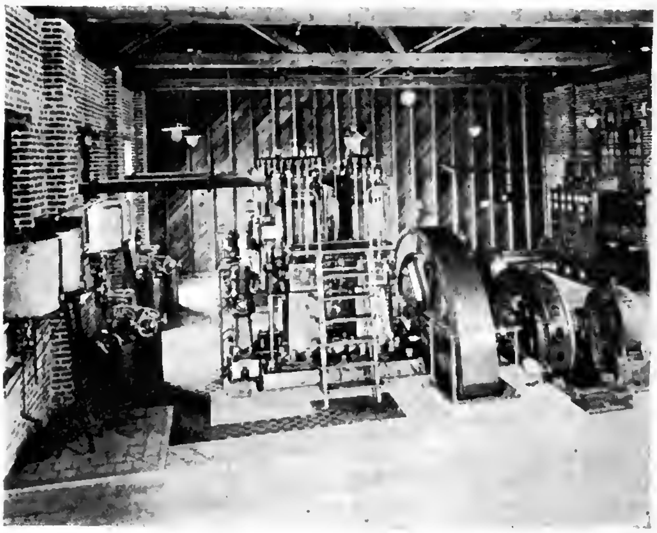
Forced lubrication is adopted, the oil going first to the piston, and then to the gudgeon pin.

Air Compressor

The air compressor is situated at the end of the crank shaft, and is direct driven by it. This position gives accessibility and allows the compressor to be designed according to the best practice. Flat disc valves are used, which, besides eliminating "sticking up" troubles, give a high volumetric efficiency resulting in a small power being required to drive the compressor. The air is compressed in two stages with inter-cooling, and is delivered to the running bottle, where it is throttled by hand at the outlet; this regulation of the blast determines the quantity of oil blown into the cylinders proportioning it to the load demand. In addition to the running bottle two very long starting bottles are attached to each engine; and the reserve capacity of these bottles is so large that the Duncan plant can be started up a dozen times without recharging them. No trouble need ever be feared from loss of pressure, nor need provision be made for independent means of recharging the bottles. As the engines never fail to start with the first blast from the bottles, the excessive reserve of starting power is merely a safeguard against inexpert handling.

General Operation

For the operation of the plant one man per shift suffices; and it will be of interest to mention that the operators in this plant were previously quite unacquainted with the running of Diesel engines. Yet so simple and reliable is the Diesel electric station now, that in its ten months of continuous operation no trouble or mishap has occurred in this plant. Overshading even the great saving of labor and maintenance is the economy of fuel costs compared with steam plants, the actual fuel cost in the Duncan plant being approximately one-third of a cent per kw. hour.



Interior Diesel power plant, Duncan, B.C.

It might be added that the successful operation of the Duncan installation is in no small way responsible to the enthusiastic interest taken in it by the City Engineer, Mr. M. Leighton Wade.

The Kaministiquia Power Company

Rapid development of Canadian Twin Cities Due Largely to Ample Supply of Dependable Power — Latest Installation Work at Kakabeka Falls

By P. R. Farrow*

The Canadian twin cities of Fort William and Port Arthur, at the head of Lake Superior, occupy a strategical position in the commerce of Canada. During the seasons of navigation west-bound merchandise is carried largely by boat, on account of the low freight rates, and there transferred to rail, or stored for delivery during the succeeding winter months. East-bound grain, forest and mineral raw products are also transferred here, forming return cargo. The great bulk of the coal for the Middle West is brought up by boat during the summer from Buffalo and Cleveland, and transferred or stored, at immense electrically-operated coal docks.

At Port Arthur and Fort William are situated some of the largest and most modern coal docks on the continent. Upwards of 3,000,000 tons of coal are shipped through this port every year. The transfer facilities to handle this traffic must necessarily be of the very best, and electric power has here proven itself a most dependable and efficient servant. All the coal docks, of which there are five, are operated by electric power.

Grain Facilities

In the transfer and storage of grain these ports excel all other ports in the world. The storage capacity of the port is now over 45,000,000 bushels, and is being increased yearly. During the fall rush, grain is delivered day after day into the elevators at the rate of 2,000,000 bushels per day. It is then graded and transferred to boats for delivery at Georgian Bay, Lake Erie and the St. Lawrence ports.

Here again electric power performs a most important service, on account of its adaptability, efficiency, reliability and convenience. As new storage units are added to the elevator, the simple electric motor readily adapts itself to suit any location and meet any service, and yet can be centralized and controlled from one point.

On account of the location of these twin cities as a bulk-breaking and storage point for raw and finished products, it was obvious that they were destined to become large manufacturing and milling centres. The cities are now served by three transcontinental roads, and have a population of about 45,000.

The one other element necessary to complete the chain of facilities was introduced in 1906, when the Kaministiquia Power Company began delivery of electric power from their hydro-electric development at Kakabeka Falls. After nine years of operation this company can point to a record which for continuous and uninterrupted service has probably not been excelled by any other plant in Canada. Trouble, inconvenience or delay from ice, backwater or water shortage, is unknown, and from all causes the aggregate interruptions to the system have not exceeded twenty minutes in any one year. During the past year this record has been reduced to less than four minutes and the company have further plans and improvements under consideration by which they hope to reduce their service interruptions to the vanishing point.

The details of the electric power plant are covered in considerable detail below. The plant is located at Kakabeka Falls—a beautiful falls with a sheer drop of 110 feet, located some twenty miles northwest from Fort William, on the line of the Canadian Northern Railway. The water is brought overland for a distance of one and one-quarter miles in reinforced concrete aqueducts, of which three are now completed. At the brow of the hill, just above the power house, the aqueducts empty into a regulating reservoir or forebay, in which are located the recently installed automatic controlling gates for each of four steel penstocks, through which the water is carried to the power house turbines. The turbines operate under a net head of 180 feet. The power is generated at 4000 volts, transmitted at 25,000 volts to Fort William and Port Arthur, and there distributed at 25,000 volts and 2,200 volts.

The original installation was commenced in 1905, and in the fall of 1906 the first two units of 4,400 kv.a. each were completed and placed in operation. In 1911 the business of the company had expanded at such a rate as to justify the installation of a third unit. In 1913, taking advantage of the temporary trade depression, with its resultant low costs for equipment and installation of plant, the company commenced the installation of a third concrete aqueduct, and a fourth unit of 9,375 kv.a. This was completed and placed in operation in the fall of 1914.

While there has been a temporary falling off in manufacturing in the twin cities, as elsewhere, this has been largely counterbalanced by the manufacture of war munitions, and by the abnormally heavy grain movement. The 1915 grain crop exceeded all anticipations, and has been phenomenal in the history of the country. Ordinarily the bulk of the grain rush is over in December. It is estimated that it will keep all available rolling stock busy all winter, and all the railroads and boats busy all next summer, to get the grain out of the country before the next grain crop comes in. The railroads are the greatest distributors of the wealth of the country we have. This great movement of grain cannot but have a very beneficial and sustaining effect on the trade of the country throughout the coming year.

Summary

The following data covers the additions to the plant of the Kaministiquia Power Company, Limited, at Kakabeka Falls, during the period between June, 1913, and September, 1914, which consist of a reinforced concrete aqueduct, one and one-quarter miles long between the intake and forebay reservoirs; the installation of steel butterfly gates as head gates of the penstocks, in the forebay; the erection of a steel penstock, 740 feet long, eleven feet diameter, between the forebay and the power house, with a concrete covering; extensions to workshops and valve house; erection of a special battery house near the forebay to control the steel gates therein; erection of a 12,500 h.p turbine and 4,000 volt generator; five step-up transformers, with necessary switching and indicating switchboard apparatus; two storage batteries with their switchboards; the installation of an improved lighting system in the power house and various incidental work in connection with the above.

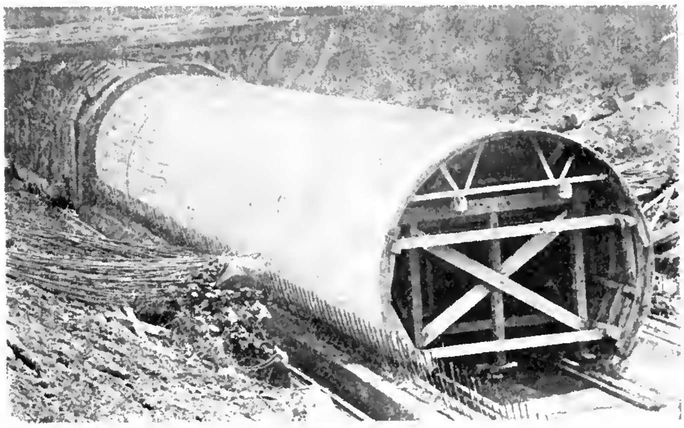
Aqueducts

The centres of the inside and outside of this pipe, which is an equivalent area to a 10-ft. diameter circle, are vertically offset one and one-half feet. The interior cross section of the pipe is that of a circle 10 ft. 6 in. diameter, with a segment cut from the bottom four feet from the centre, forming a flattened base. The bottom slab thus formed, is ten inches thick and is carried out until a line sloping at eight degrees with the vertical approaches eight inches minimum

* Power House Superintendent.

to the interior. At the top the concrete is six inches thick and an arc with radius 6 ft. 1 in. meets the sloping sides and completes the section of the pipe.

Grade and Ground.—The formation of the surface upon which the pipe lies is very varied over its length of 6,500 feet, running from solid rock near the intake, through clay, boulders, swamp, quicksand, hardpan and gravel with boulders, to the forebay. For the first 500 feet from the intake, the pipe practically follows the river bank and at two places the bank had to be filled in with rock and a concrete retaining wall built on the bank to form a support for the base, one of these fills was 30 feet, maximum depth. At the intake the pipe runs below the level of the river bed and a retaining wall, to deflect ice and otherwise protect the pipe, was built up from rock from the aqueduct base level. A drain was also built from the intake to a point in the river 450 feet below to obtain the proper fall and to drain all aqueducts when necessary, for inspection. For 2,000 feet the aqueduct runs level from the intake over a rock bed, it then dips gradually to 4.5 feet below grade through a rock fill overlying clay and boulders for 1,000 feet, then for 900 feet it rises to 3.5 feet above the preceding level, passing through an excavation of hardpan and gravel; for the next 500 feet the level falls again through a fill over a quicksand. This portion of the grade was sheet-piled by double 2-inch planking driven four feet outside the base of the pipe and provided with drainage to take off water, but so arranged as to prevent the sand working out from under the base of the pipe. The pipe then passes over gravel, which was levelled for 900 feet, and into a deep cut of gravel and boulders, varying from six to nine feet deep and fourteen feet wide, which runs practically level to the forebay.



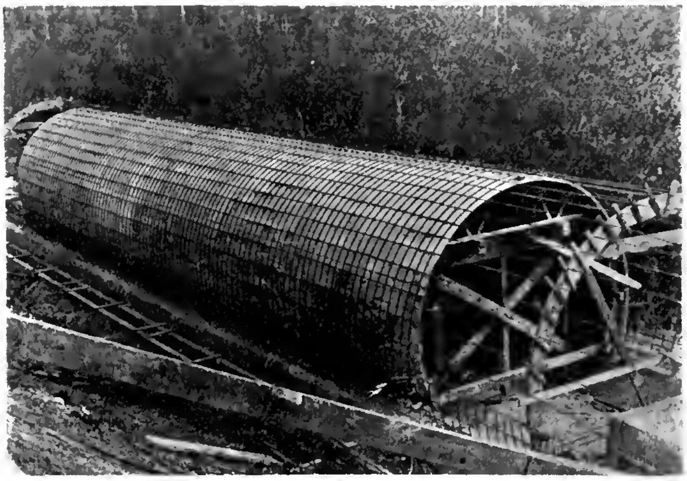
Inner form in place, outer form and pouring platform in background.

Concrete and Reinforcement.—The concrete aggregate consisted of one part of cement, two parts of washed sand, screened to pass through a ¼-in. sieve, and four parts of gravel screened between ¼-in. and 1-in. sieves. The cement, purchased on acceptance tests from the Canada Cement Company, was from one mill, and of a uniform quality, was required to pass the C. S. C. E. tests for Portland Cement, and to be of slow setting quality. The quantity of concrete used for the pipe amounted to 1.2 cu. yds. per lineal foot. The reinforcement was composed of one-half inch circular steel bars of standard specifications, spaced longitudinally from 12 in. to 15 in. apart and transversely from 5¼ in. to 6 in. apart, tied with No. 14 gauge annealed iron wire at all joints and lapped 12 ins. at ends of bars and firmly tied. No expansion joints were provided but it was hoped that sufficient hair cracks would develop to allow for contraction and prevent excessive leakage.

Forms and Centres.—The forms for moulding the pipe consisted of fifty-foot sections of steel framework, divided into three parts, running on wheels on special tracks along the pipe line, supporting a galvanized iron lined wood framework properly braced upon the steel frame, but collapsible by removing a few bolts. Over all was placed a wooden platform with central openings to allow the concrete to be deposited from carts directly into the form. The interior forms were wood, steel braced, and solid for the upper quarter section of the arc. To these were hinged side segments braced laterally when the forms were erected. The whole of the interior form was collapsible and was carried upon a track and a special carriage along the floor or bottom slab of the pipe, after it had been constructed. The forms for the bottom slab consisted merely of sides to support the concrete from the outside, lengthened to hold the transverse reinforcement in place, and a special interior form to bring the sides up 10 inches above the base before setting the upper forms.

Concrete Plant.—Two No. 2½ Smith concrete mixers, a 1/3 cu. yd. clam shell bucket, a two-stage, 25 h.p. centrifugal pump, one duplex pump, all electrically operated by three-phase, 550 volt alternating current, an electrically operated hoist, and a tower for washing and screening gravel and sand, formed the plant necessary to construct the aqueduct. A three-foot gauge railway, with eleven wood and steel contractors' dump cars was used to deliver material, and finally to cover the pipe, after completion, with three feet of earth covering as a protection from frost.

Method of Construction.—After grading and filling had been completed, in 1913, and allowed to settle all winter, the bottom slab, a simple slab 10 ins. thick, was laid after placing side forms. All reinforcement were bent at the works, from proper lengths of rod supplied, on a special bending machine. A centre form was placed and the sides brought up ten inches to form a support for the large forms of the superstructure. After the whole bottom slab had set for eighteen hours the forms were removed and the track laid for the upper forms, on the interior, directly upon the concrete slab and on the exterior upon a thin slab of concrete brought to the correct grade. The interior forms were then set for a distance of fifty feet, braced to the lower slab at the correct height and the longitudinal and transverse reinforcement applied and tied in place, with properly staggered and overlapped joints. The side and top form was then brought up, the sides cleaned and closed for concreting, set in place and braced on the lower section to prevent springing. Concrete was then placed on each side equally through small doors in the upper curve. When full to the level of the doors they were closed, and concrete poured from the top,



Transverse and Longitudinal reinforcing in concrete aqueduct—
Kaministiquia Power Co., Kakabeka Falls.

through a four-foot opening, until full. The top was then finished off over the open section by trowels. The whole operation of concreting took from 2½ to 3 hours for each 50-ft. section. The forms were ready for removal twenty-one hours after the concreting was finished. Three sections of fifty feet of forms were built, with an extra interior section enabling, even under the most difficult circumstances, one hundred lineal feet of pipe to be completed per working day, after all preliminary work had been completed. The pipe was finished by plastering all defective work and applying three coats of cement wash to the interior surface.

Vents and Drains.—14-in. drain valves were placed at each end of, and at two low points along the length of, the aqueduct, serving to empty the pipe, when closed off at each end, for inspection. Wooden stop logs form a barrier both at the intake and forebay ends when it is necessary to inspect the interior. Air vents are placed at three high points and serve to discharge accumulations of air carried by the moving water and to admit air freely when the water level falls. These consist of 8-in. diameter pipes screwed into cast nipples attached to the reinforcement. The whole is surrounded by a wooden framework to protect from injury and prevent early freezing in winter. Artificial heat is applied in winter to keep the pipes free of ice. The drain valves are protected by concrete walls with a wooden housing at the top, and are operated by long handles from the level of the earth covering on top of the pipe; sufficient room is provided at the bottom of the concrete pit to remove the valve for repairs when necessary.

Materials.—The gravel and sand for the concrete was obtained from pits on the company's property and separated and washed in one operation by dumping the excavated material into chutes, where water carried it over properly adjusted screens. From thence the gravel and sand was carried to bunkers and the water and waste material allowed to settle, the remanant being used for covering the completed pipe.

A special covering of three feet of earth was placed over the pipe as soon as completed, to protect the concrete while setting, from the sun, and to prevent frost in the winter

First completed section of aqueduct. Buggies used for conveying concrete from the mixers on pouring platform—Forebay in background.

from penetrating the pipe. The cover has been seeded to grass to hold snow in the winter. The necessary forms were built at the work, a sawmill with a circular saw, planer and band saw being provided to make the necessary material.

The reinforcement was provided in proper lengths by the mill, and bending machines in the field shaped all transverse bars.

Organization.—The whole work was in charge of Mr. Geo. Lewis, with an engineer for laying out the grades and levels, a general foreman, and a gang foreman on each section of the work; a timekeeper and storekeeper completed the staff. Inspection and testing was conducted by the engineer and writer, the company's superintendent.

Invert completed and track laid for inner forms. Outer forms being placed—Note reinforcing rods to join the invert to the superstructure.

(Continued in February 16 issue)

Personal

Mr. James McHaney has been appointed town engineer of Southampton, Ont.

Mr. Mark Workman has been chosen to succeed Mr. J. H. Plummer as president of the Dominion Steel Corporation. Mr. Plummer, whose health has been poor for some months, has retired to take an extended holiday abroad.

Mr. O'Hara, engineer of the Cloverdale municipality, B.C., has resigned to accept another appointment.

Mr. Herb L. White, formerly manager for The Superior Construction Company of Sudbury, Ont., and later of Hobon, Ont., has resigned to accept a position in Buffalo.

Mr. R. J. McMurray, one of the inspectors in the Toronto city architect's department, has enlisted in the Third Division Ammunition Column. Mr. McMurray has been with the department about a year and a half. He is the third member of this department to enlist for overseas service

Obituary

Thos. E. Baker, contractor, Prince Albert, Sask., died recently.

W. Ernest Barker, a well-known carpenter and builder of St. John, N.B., died on January 27.

Pte. Oliver Beech, formerly assistant to the city engineer of Macleod, Alta., died from wounds received in action recently. He was 28 years of age.

Mr. Chas. Bodley, Sr., a well-known resident of Mount Forest, Ont., died recently, in his 86th year. He was the designer and constructor of most of Mount Forest's old public and private buildings.

Mr. Egbert Fulljames, who with his brother carried on a contracting business in Cranbrook, B. C., for some years, died recently.

Senator George Riley died on January 19th at Victoria, at the age of 73. He was born in St. Catharines, Ont., where for some time he was engaged as a merchant. In 1885 he went to Victoria, where he became paymaster with the contracting firm of Bell, Larkin & Paterson, which was at that time engaged in the construction of the Esquimalt and Nanaimo Railway. This engagement marked the beginning of a successful business career extending over forty years.

The death is announced of Mr. G. Colin Carman, a well-known resident and civil engineer, of Cornwall, Ont., on January 21st, in his eightieth year. Mr. Carman was born in Cornwall, and commenced his professional career on the construction of the Intercolonial Railway, being assistant engineer on the section between Riviere du Loup and Hamilton, N.B. He was engaged in both the location and construction of the British Columbia end of the Canadian Pacific Railway, and was engineer in charge of the section on the Upper Fraser River, from Spence's Bridge to Yale. From 1890 to the time of his retirement a few weeks ago he was on the engineering staff of the St. Lawrence Canals. He was resident engineer in charge of the construction of the Sheik's Island Dam, and also had charge of the construction of the 800-foot lock at Iroquois on the Galops Canal.

Mainly Constructional

East and West—From Coast to Coast

The Bancroft Marble Quarry, Belleville, Ont., are working overtime in filling rush orders.

The Stratford, Ont., Builders' Exchange held a successful meeting on the 27th ult. in their rooms in the Worth Block.

The Sombra Township Council have recommended the appointment of Mr. George A. McCubbin as township engineer.

The building law of Fredericton, N.B., is to be amended, more restrictions being placed on the repairing of frame buildings.

The Frontenac Moulding and Glass Company, Limited, has been incorporated with a capital stock of $250,000 and head office at Toronto.

The second of the three spans of the new steel bridge being built at Trenton, Ont., to replace the historic wooden structure, is now placed.

Seven hundred and eighty-seven thousand five hundred and ninety-five dollars was spent on trunk sewers in Burrard Peninsula, B.C., during the year 1915.

The Bank of Hamilton announce their intention of razing their old building at Winnipeg and erecting a handsome five-storey structure on the same site.

The financial statement of the Canada Cement Company, Montreal, for the year 1915, shows net earnings of $1,724,013—an increase of $224,954 over those for 1914.

The Ontario Granite and Marble Workers' Association held their fourth annual banquet on February 1st in the Carls-Rite Hotel, Toronto. Sixty members were present.

In January, 1916, the city of Winnipeg issued nineteen building permits, of an aggregate value of $17,700. In January, 1915, the value of building permits issued was $14,800.

The new Welland Canal is rapidly nearing completion. Of the nine sections into which the 25-mile job is divided, the four most important and expensive are well under way.

The applications made to the Toronto city architect for building permits during the week ending February 26 showed a considerable advance on the previous two weeks. Forty-seven persons applied for permits, amounting to $137,340.

In a recent case at Windsor, Ont., the judge gave a ruling that where sidewalks were originally corrugated and have been allowed to wear smooth the city is responsible for accidents. This decision also applies to glass areas in the sidewalks in front of stores.

The annual meeting of the American Society of Civil Engineers was held in New York from January 14 to 21. The Society is in a flourishing condition financially, and its present membership is placed at 8,000. Mr. E. L. Corthell, of New York City, was elected president for the ensuing year.

Canada spent nearly twenty-five million dollars during the last fiscal year on capital account for Government railway construction and permanent improvements, and five and one-half millions on canals, bringing the total Government expenditure, prior to and since Confederation, on capital accounts for railways, up to $352,947,000, and for canals to $112,472,000.

The Elgin County Council have decided to pass a by-law to take advantage of the provision of the Highways Improvement Act in order to build good roads throughout the county. The by-law is not to become operative until January 1, 1917, and in the meantime a comprehensive plan will be prepared for designating the roads and the amount of improvements required.

Welland County Council have designated roads to be built on the county system this year estimated to cost $101,000. Last year $231,367.04 was expended on the good roads system, upon which the Government grant amounted to $77,222.35. About eighty-three miles has been completed to date out of a total of 133 miles, and the cost averages about $5,000 per mile.

Commissioner Harris does not recommend the installation of Imhoff tanks at the Toronto sewage disposal works—partly because he is not certain that this is the best system for overcoming the smell nuisance, and, partly on account of the cost, which would be from five to six million dollars. In his opinion the activated sludge process with which the city is experimenting offers better promise of results.

Among the new companies recently registered at Halifax, N.S., under the Joint Stock Companies Act is Plaster Quarries, Limited, a corporation formed to acquire and take over from G. C. Fletcher a gypsum deposit at Island Point, C. B., and manufacture and deal in gypsum and its products. Registered office at Sydney. Capital $300,000 in 300,000 shares. Shareholders named: Wm. A. Wood, Wm. Johnson, Jr., and Alexander Campbell, Montreal.

Subletting of Manitoba Government contracts will be made practically impossible by a bill called a "Fair Wage Act" which the Hon. T. H. Johnson has introduced into the Manitoba legislature. It provides for the establishment of a fair wage board to draw up a fair-wage schedule annually, and in order to hold employers responsible for the conditions it declares that government contracts may not be sublet, assigned, or otherwise disposed of except with the consent of the minister. Assignments for the benefit of creditors may be made, but no others unless the approval of the minister has first been obtained.

The Shawinigan Laboratories, Limited, has been formed, with a capital of $25,000, for research purposes in connection with electro chemical, mechanical, electrical, metallurgical and electro-metallurgical engineering. Messrs. Howard Murray, W. S. Hart, Julian C. Smith, J. C. King, and F. T. Kaelin, of the Shawinigan Water and Power Company, are among the incorporators. It is proposed to continue operations at Shawinigan Falls, where much experimental and research work has been carried out in the laboratories. It will be remembered that some of the gentlemen named are interested particularly in the establishment of electric furnaces for the manufacture of high grade steel.

Tenders and For Sale Department

Hydro Tenders Wanted

Sealed tenders, marked "Tenders for Lead Covered Cable," addressed to the Chairman, The Toronto Electric Commissioners, will be received until noon, **Wednesday, February 16, 1916.** Each tender must be accompanied by a marked cheque as called for in the form of tender. Specifications and form of tender can be obtained at the office of the purchasing Agent, 15 Wilton Avenue. The lowest or any tender not necessarily accepted. 6-6

Hydro Tenders Wanted

Sealed tenders, marked "Tenders for Pole Type Transformers," addressed to the Chairman of the Toronto Electric Commissioners, will be received until noon on **Wednesday, February 16, 1916.** Each tender must be accompanied by a marked cheque, as called for in the form of tender. Specifications and form of tender can be obtained at the office of the Purchasing Agent, 15 Wilton Avenue. The lowest or any tender not necessarily accepted. 6-6

CITY OF MONTREAL

Refined Asphalt

Tenders, under sealed envelope, addressed to the Board of Commissioners and deposited in their office, at the City Hall, will be received until noon, **Thursday, February 24th, 1916,** for the supply and delivery of refined asphalt.

The quantity anticipated is about six thousand (6,000) net tons. It is distinctly understood that this quantity is but approximate, and the Board of Commissioners reserves the right to increase or decrease said quantity in any amount at its discretion without entitling the Contractor to any claim whatsoever.

Copies of specifications and forms of tenders may be obtained by the interested parties at the office of the Superintendent of Purchases and Sales, and all necessary information will be given at the Chief Engineer's Office.

All tenders not made on the form furnished for that purpose by the City of Montreal, and not sent in the printed envelope also furnished for that purpose shall not be entertained.

No tenders shall be considered unless the same be accompanied by a cheque accepted by an incorporated Canadian Bank payable to the City of Montreal, for a sum representing 10 per cent. of the total amount of the tender, which tender and cheque shall be enclosed in said envelope.

The lowest or any tender will not necessarily be accepted.

The tenders will be opened in the presence of the interested parties by the Board of Commissioners deliberating in its Meeting Room, at the City Hall, at the first regular meeting of the said Board, following the reception of the said tenders or on the date above mentioned, if the Board is sitting.

By order of the Board of Commissioners.

L. N. SENECAL, Secretary.

Board of Commissioners' Office,
City Hall,
Montreal, February 1st, 1916. 6-7

WANTED

Six contractors' dump cars and dinkey. Give particulars. Box 313, Contract Record, Toronto, Ont. 6-7

Tenders Wanted

Sealed tenders for all trades, with the exception of structural steel, in connection with the erection of the New Princess Theatre, Toronto, will be received until 5 p.m., **Saturday, February 12, 1916,** at the office of the undersigned.

Structural steel tenders will close at 5 p.m., Saturday, February 5, 1916.

Tenders to be submitted on forms to be supplied.

Plans and specifications may be seen at the office of Charles J. Read, Rooms 203-4 Confederation Life Building, Toronto, Ont.

C. HOWARD CRANE, Architect,
CHARLES J. READ, Associate Architect.
4-5-6

Sealed tenders addressed to the undersigned, and endorsed "Tender for Lock Gates at East River Lock, N.S.," will be received at this office until 4 p.m., on **Monday, February 28, 1916,** for the construction of Timber Lock Gates and their equipment for the East River Lock, near New Glasgow, Pictou County, N.S.

Plans and forms of contract can be seen and specification and forms of tender obtained at this Department, and at the offices of the District Engineers at Antigonish, N.S.; Halifax, N.S.; Shaughnessy Building, Montreal, P.Q.; Confederation Life Building, Toronto, Ont., and on application to the Postmaster at New Glasgow, N.S.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be **given.**

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

NOTE.—Blue prints can be obtained at the Department of Public Works by depositing an accepted bank cheque for the sum of **$20.00,** made payable to the order of the Honourable the Minister of Public Works, which will be returned if the intending bidder submit a regular bid.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, January 27, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—91583. 5-6

For Sale

Large manufacturing company in the United States specializing in concrete machinery wants to sell outright a full set of drawings, patterns, and other information in reference to building and marketing concrete mixers. Good opportunity for Canadian manufacturer. Box 296, Contract Record and Engineering Review, Toronto, Ont. 4-6

Notice to Contractors

Supplies Wanted

Sealed tenders addressed to the Chairman and Members of the Water Works Committee will be received by the Secretary of the Water Works Committee, City Hall, Ottawa, up to 4 p.m., **February 24th, 1916,** endorsed "Tender for Brass-work, Cast Iron Pipe, Lead Pipe and Pig Lead, Oils and Grease, Special Pipe Castings or Valves," as the case may be.

Any tender received after the above stated time will be declared informal.

Specifications, Form of Tender and full particulars may be obtained on application to the City Engineer's Office, City Hall, Ottawa.

The Corporation does not bind itself to accept the lowest or any tender.

R. L. HAYCOCK,
Acting W. W. Engineer.

Ottawa, February 4th, 1916. 6-6

Township of Brantford

Fonger and Barton Bridges

Sealed tenders, clearly endorsed on the outside, will be received up to noon on **Saturday, February 26th, 1916,** addressed to the Township Clerk, County Building, Brantford.

"A"—For reinforced concrete abutments for Fonger Bridge, containing 225 cubic yards of concrete, and 18,000 lbs. square cold twisted steel reinforcement.

"B"—For steel superstructure, Class "A" loading, clear waterway 70 feet, clear roadway 16 feet, with reinforced concrete deck and latticed handrailings.

"C"—For reinforced concrete abutments for Barton Bridge, containing 165 cubic yards of concrete and 11,500 lbs. square cold twisted steel reinforcement.

"D"—For steel superstructure, Class "A" loading, clear waterway 80 feet, clear roadway 16 feet, with reinforced concrete deck and three line pipe handrailing.

Each tender must be on the prescribed form and accompanied by a marked cheque for 5 per cent. of the amount of the tender, made payable to the Treasurer of the Township of Brantford.

Plans and specifications may be seen at the office of the undersigned, Room 4, Temple Building, Brantford, from whom tender forms may be had.

ALAN MAIR JACKSON,
Township Engineer.
6-7

POSITIONS VACANT

CITY ENGINEER WANTED.—Applications for position of city engineer will be received until **March 1st, 1916.** Salary, $1,800 per annum. Send copies, not originals, of references, etc. Jos. McCartney, City Clerk, Galt, Ont. 5-6

AGENTS WANTED

Canadian sales agents wanted by large company manufacturing road making and contractors' machinery. Box 297, Contract Record and Engineering Review, Toronto, Ont. 4-7

Quarry Machinery For Sale

1—No. 6 Kennedy Crusher with extra shaft and head; capacity 50 to 80 tons per hour.
1—revolving screen.
1—main drive belt.
1—60-ft. elevator complete.

For particulars address Box 311, Contract Record, Toronto, Ont. 6-7

Made in Canada

Kennedy Road, Scarboro Township,
York County, Ontario.
Tarvia filled macadam.

Cheaper than Plain Macadam—

TARVIA is always cheaper in the long run to bond a macadam road with than water. Sometimes Tarvia as a binder does not add anything to the first cost.

The York County Highway Board, York County, Ontario, built about five miles of Tarvia macadam in 1915 and found it two cents a square yard cheaper than water-bound macadam cost them in 1914.

Such figures are not unfamiliar. The Tarvia displaces a certain amount of stone and reduces the amount of rolling required. The excessive use of water, often difficult to provide, is done away with. The Tarvia often makes possible the use of a cheaper stone which may not make a good road by itself but will give excellent results when there is a Tarvia matrix to prevent internal attrition.

Plain macadam is not fitted to stand the stresses of modern traffic but a tarviated road is automobile-proof. The swiftly driven wheels which disrupt a plain macadam surface, merely roll down a tarviated macadam and make it smoother. The tarviated surface is waterproof and frost-proof, and will not ravel when rain torrents sweep down steep hills.

There are three kinds of Tarvia. "Tarvia-X" is very heavy and dense, used as a binder in road building as in the above instance, and the most thorough and permanent of the Tarvia treatments. "Tarvia-A" is a lighter grade, used for hot surfacing applications. "Tarvia-B", which is fluid enough to be applied cold with modern spraying apparatus, is for dust prevention and road preservation.

In addition to the five miles of "Tarvia-X" macadam mentioned above, the York County Highway Board in 1915 coated six and one-half miles of the Kingston Road with "Tarvia-B." This is one of the best roads leading out of Toronto.

Booklets on request. Address our nearest office.

Special Service Department.

This Company has a corps of trained engineers and chemists who have given years of study to modern road problems. The advice of these men may be had for the asking by anyone interested. If you will write to the nearest office regarding road problems and conditions in your vicinity the matter will have prompt attention.

Power Plants, Electricity and Telephones

(Continued from page 46)

Tisdale Township, Ont.
A by-law authorizing the purchase of an electrically driven fire pump has been passed. Clerk, W. H. Wilson, South Porcupine, Ont.

Toronto, Ont.
Tenders on the supply of lead covered cable will be received until February 16th by the Toronto Hydro Electric Commissioneds, 226 Yonge Street. Specifications, etc., at office of the Purchasing Agent, 15 Wilton Avenue.

The Toronto Hydro Electric Commissioners, 226 Yonge Street, will receive tenders until February 16th on the supply of pole type transformers. Specifications at office of the Purchasing Agent, 15 Wilton Avenue.

Wheatley, Ont.
The Independent Telephone Company are considering improvements and extensions to their systems during the year. Secretary, J. W. Kennedy.

CONTRACTS AWARDED

Sherbrooke, Que.
The City Council have awarded the contract for the supply of transformers to the Canadian General Electric Company, 158 St. Antoine Street, Montreal.

Late News Items

Hespeler, Ont.
The tool factory of A. B. Jardine & Company, Guelph Street, has been destroyed by fire. Loss, $75,000, principally on the shell plant.

London, Ont.
Plans are being prepared by Watt & Blackwell, Bank of Toronto Building, for alterations to a store for Miss F. Mitchell, 114 Dundas Street. Estimated cost, $10,000.

McGillivray Township, Ont.
Plans are being prepared by F. W. Farncomb, Edge Block, London, for a drainage scheme to be constructed jointly by the Townships of McGillivray, East Williams and Stephen. Work will start in the spring. Approximate cost, $15,000.

Montreal, Que.
The Board of Control will receive tenders until February 15th for the erection of a pump house and installation of a pump for the Notre Dame de Grace Sewer. Specifications, etc., at office of the Engineer, D. McLeod, City Hall.

New Liskeard, Ont.
Fire has totally destroyed the business block owned by F. O'Brien. Loss, $50,000.

Ottawa, Ont.
The City Council have passed Waterworks Department estimates of $50,000 for short watermain extensions on various streets throughout the city and $189,000 for construction of watermains under the Lee Distribution Scheme. Engineer, R. L. Haycock.

Port Moody, B.C.
In connection with the construction of a steel plant and rolling mills for the Port Moody Steel Works, Limited, Standard Bank Building, Vancouver, the contract for erection of main building, construction of a wharf and pile driving has been awarded to Henry Peterson, 16 Hastings Street E., Vancouver.

St. Catharines, Ont.
The contract for masonry required in the erection of a shop for the Metal Drawing Company, Race Street, has been let to Newman Bros., 71 St. Paul Street, and the carpentry to R. B. Williams, Beecher Street. Work has been started. Steel sash will be purchased by the masonry contractor. Architect, A. E. Nicholson, Queen Street.

Walkerville, Ont.
William Woolat, Jr., Kildare Road, has commenced the erection of a residence, estimated to cost $6,000. Stucco and brick construction. Work is being done by the owner and S. Keyser, 92 Moy Avenue, Windsor.

Windsor, Ont.
Work is about to start on the erection of an addition to the agricultural building at the Race Track for the Windsor & North Essex Agricultural Society. The masonry contract has been let to R. Wescott, 55 Oak Avenue. Sub-contracts not yet awarded. Frame construction, concrete foundation, composition paper roofing. Estimated cost, $6,000.

Winnipeg, Man.
The Presbyterian Church at Point Douglas has been practically destroyed by fire. Loss, $15,000. The congregation intend to rebuild and work will probably start immediately. Pastor, Rev. R. Boyle.

This is No Time to Take Chances

The British Empire, of which Canada is an important part, is in a death-grapple with Germany.

There is no possible reason for doubting that this same Germany will, if she can, destroy the power of England.

The destruction of British power inevitably means that Canada falls under the control of some other nation.

Ultimately, if not immediately, that nation would be Germany—for, if Germany wins this war and cripples England, there is not sufficient world-power to withstand her aggressions.

Neither is there any doubt that in starting this war the ultimate ambition of the present German military power was to subdue the whole world.

Of course this war has developed into a much bigger business than Germany dreamed when she willed it on Europe. She hoped to achieve her ambitions step by step. But the Allies unexpectedly forced her hand, and she is clever enough to grasp the situation. She sees it clearly to-day—now or never—life with power, or death with shame.

Germany therefore fights to-day a fight for very existence—the fight of a hungry, maddened jungle-beast thwarted of its prey and driven to bay.

Can we Canadians, as sane beings, fighting with such an opponent—clever, powerful, resourceful, unscrupulous, beast-like—can we, I say, afford to take any chances? I don't say that any man of German blood in the employ of the Government at Ottawa is disloyal to Canada—I don't know. But I do say—it's possible. I do say that in the breasts of these men love of their native land would be only human. I do say that, with the very best of intentions, these men of German extraction are more likely to be the medium through which important military information might leak out. I do say that Germany's methods in the conduct of this war, in many directions, have led us to view with an irrepressible feeling of suspicion the acts of even our closest friends who may have German blood in their veins. I am willing to admit that this feeling is often unjust; but Germany has willed it so—even as she willed the war.

The continuance of any men of German birth or close German connection in any position of trust in Canada is entirely indefensible. Remove them at once. Treat them with all courtesy, pay their salaries if you will, reinstate them when we've won the war, but now—remove them.

Make it as impossible for them to do us harm as if we believed them guilty of the desire.

We are taking a chance when our life is at stake. It is a foolhardy chance, because there is nothing to be gained. Remove them as a precautionary measure.

I know that I express the sentiments of more than ninety-nine per cent. of the people of Canada when I demand from our Government the instant removal of these men from office, the immediate institution of adequate protection of all our public buildings and works, and the immediate segregation of such small elements in our population as give indication of German sympathies and who, in so doing, may interfere with our recruiting or may hinder the progress of the war in the smallest measure whatsoever.

And this latter applies to Waterloo County as elsewhere. Why should one of the most loyal sections of the whole Dominion be singled out for the humiliations of the past few weeks? "He that is not with us is against us." High or low, rich or poor, let us not forget for an instant—it's a fight to the death.

Montreal Harbor Improvements

Two new main projects are dealt with in the annual report of the Montreal Harbor Commissioners. These are the erection of an eight-storey warehouse and the electrification of the harbor railway terminals. The Commissioners refer to the need of warehouse accommodation so that goods can be received during the summer months when freights are advantageous, and held in order to give speedy delivery when required. The Commissioners have had under consideration plans for an eight-storey warehouse, to be situated in a central position on the harbor. The warehouse would have all the advantages of modern design. A railway car elevator hoist would take cars to the unloading platforms at each floor. The Commissioners would undertake to handle freight by railway car from the sheds to the warehouse, or vice-versa. Cars for delivery to outside points could be loaded at the different floors and shipped without any intermediary cartage.

With regard to the electrification of the railway terminals, the report states: "The increase in the railway traffic of the port and the mileage of trackage in operation makes it important to proceed with the utmost despatch in establishing facilities which will not only retain Canadian trade, but which, by their superiority over those provided at competitive ports, will attract additional business. With this object in view the Commissioners have, during the past year, devoted much time and thought to a study of a scheme for the complete electrification of the harbor railway terminals, visiting and inspecting in the meantime the electric freight terminals of the New York Central, Pennsylvania, and New York, New Haven and Hartford Railroads. at New York, Oak Point, New Rochelle, etc., where the application of electricity had proved successful in the movement of freight at the various terminals. It was also ascertained that, in addition to the primary object of overcoming the smoke nuisance, the application of electricity had proved that it had, among many others, the following advantages over steam for railroad terminal traction:—Economy in operation and maintenance; flexibility of control; availability for immediate service; fewer units required for equal service; elimination of corrosion of steel and galvanized iron by acid gases; fire danger reduced; and standby losses much lowered. As a result of this investigation, an expert electrical engineer has, for some time past, been engaged in studying, on the ground, the railway conditions of the port, and preparing a report as to designs, types and estimates, upon receipt of which it is proposed, should the report confirm the conclusions arrived at by the Commissioners, to proceed at once with the work of completely electrifying the Montreal Harbor terminals, upon the consummation of which Montreal will have the distinction of being the first port in the world possessing a complete system of electrified freight terminals."

Included in the work to be done during 1916 is the reconstruction of the Victoria Pier, which will be completed during the present year, the development of this pier and the market basin giving 2,700 lineal feet of high level quays for the ocean steamers, with a depth of thirty-five feet at low water, and 4,000 lineal feet on low level quays for river vessels, ferries, etc. The program of the Commissioners also includes the lengthening of the King Edward, the Alexandra and Jacques Cartier piers to 1,200 feet each, continuation of the high and low level wharves, very large works to change the St. Mary's current, and a bridge across from the Mackay pier to St. Helen's Island and thence across to the South Shore. The proposed bridge will be ninety feet wide and will provide two footpaths, a roadway, street car tracks, and railway lines, the latter being electrified in the same manner as the rest of the harbor railways, and connecting up with railways on the South Shore. The electric engine used will be of the d. c. 1,200 volt locomotive type. It has a length of 39 feet 6 inches, a height over the cab of 12 feet 4 inches, and from the trolley to the ground of 14 feet 6 inches. The width over all is 10 feet 1 inch. The weight of the electrical equipment is 60,000 lbs., and of the mechanical equipment 140,000 lbs. The haulage capacity of the engine will be roughly about a thousand tons. A portion of the tracks along the main frontage will be elevated, while the remainder will be surface tracks.

The disbursements on capital account in 1915 were $1,850,001.40, on the following works of improvement:

Grain Elevators	$ 636,950.65
Wharves, Piers and Basins	565,683.72
Harbor Dredging	269,704.48
Real Estate	158,636.07
Harbor Railway	145,065.93
New Plant	37,265.17
Permanent Sheds and Hoists	36,695.38
Total	$1,850,001.40

A Conundrum of the Day

"Should the chief intelligence officer of the war department of Canada be a German, with brothers in the German army?

"Should there be other Germans in the Government service here? A number there are.

"Is Canada at war with Germany or playing marbles?"—Ottawa Journal.

Good! and for heaven's sake will Ottawa cease playing politics?

Toronto Branch C. S. C. E.

The regular monthly meeting of the Toronto Branch was held in the Society's rooms at the Engineers' Club, 90 King Street West, on Thursday, Feb. 10th. The recently elected chairman Mr. G. A. McCarthy occupied the chair. Mr. G. R. G. Conway, M. Can. Soc. C. E., consulting engineer, Toronto, gave an informal lecture on "Recent Dam Construction in British Columbia," with particular reference to work with which he has been associated as Chief Engineer of the B. C. E. R. Co.

The lecture was illustrated with a fine series of lantern views and described the construction of the Bear Creek Dam on Vancouver Island which forms one of a number of dams built for the storage of water at Jordan River, 40 miles west of the city of Victoria, for the hydro-electric plants of the British Columbia Electric Railway Company. This dam is 1,020 feet in length and 50 feet in height, with 2½ to 1 downstream slope and 3 to 1 upstream slope, and contains 148,400 cubic yards of material. The dam was built by the hydraulic process and impounds 328 million cubic feet of water, the top elevation being 1,483 feet above sea level.

Five miles below Bear Creek dam has been constructed the Jordon River dam of the "Ambursen" type, which is the highest dam in Canada, the extreme height being 128 feet. It is so far the second highest reinforced concrete dam that has been built, the highest being the LaPrele dam in Wyoming which has a maximum height of 136 feet. The Jordan River dam is 891 feet in length with a spillway 305 feet long provided with 8 feet of freeboard. It contains 21,200 cubic yards of concerte and 380 tons of reinforcing steel was used in its construction. The dam impounds 612 million cubic feet of water, the top elevation being 1,360 feet. From this dam the main water supply is delivered by flume to a forebay from which the penstock pipes are taken so as to utilise a head of 1,145 feet at the power house where impulse wheels have been installed to a capacity of 25,000 horsepower.

Mr. Conway also described the construction features of Coquitlam dam which impounds water for the Coquitlam-Buntzen hydro-electric project of the British Columbia Electric Railway Company. This

Conference on Road Construction

For Road Superintendents and Engineers of the Province of Ontario—A four-day lecture and discussion course, thoroughly practical in its nature, covering the requirements of country road construction in all its various phases—Mr. W. A. McLean, Deputy Minister of Provincial Highways, discusses "Road Laws"

The first conference on highway construction for County Road Superintendents and Engineers, held in Toronto in February, 1915, met with such success that it was decided to continue the course again this year. The second conference was held in Toronto last week, February 8th to 11th, and judging by the good attendance, the vigorous discussions and interchange of ideas among the engineers from many Ontario counties this conference will be even more fruitful of results than the first.

Aim of the Conference

The organization covers more especially the southern portion of the Province of Ontario. The need for uniformity of methods, and for a close personal understanding between the engineers of the Department of Highways and the County Superintendents is essential for the efficient prosecution of highway improvement. This has been very successfully met by these conferences, at which practical lectures on highway construction, maintenance, etc., covering the problems of the practical man on the road have been delivered and very thoroughly discussed. The following resume of the congress proceedings endeavor to cover in the main the points brought out in discussion. Mr. W. A. McLean, Deputy Minister of Highways for the Province of Ontario, presided throughout.

* * *

ROAD CONSTRUCTION AS GOVERNED BY TRAFFIC REQUIREMENTS

Mr. R. C. Muir, A. M. Inst. C. E., opened the conference with a paper on "Road Construction as Governed by Traffic Requirements." The volume and classes of traffic are governing factors in the choice of the proper type of road. Traffic should be studied to ascertain these conditions before attempting to build. Great care should be given the sub-grade and the foundation, for the foundation in reality carries the load. In building the foundation careful attention should be given to drainage. If this is not done the bed becomes soggy and soft, with the result that heavy traffic is apt to break through the surfacing. Grades

Second Annual Conference on Road Construction for Road Superintendents and Engineers under the auspices of the Ontario Department of Public Works.—Group photograph of delegates bear an important relation to pavement; the destructive effect of heavy traffic on steep grades is a serious item. Also, damage is done to roads by horses' shoes and narrow tires; these may be remedied by the use of a flat rubber shoe for horses, and widening the tires in the case of vehicles. Again, the width of the street bears an important relation to the life of the pavement; if the street is narrow and traffic heavy it must necessarily congest, whereas if the street were wider the load would be more widely distributed. There are three general factors in the destruction of water-bound macadam roads—effect from horses' shoes and narrow tires, crushing effect of traffic, and the shear of fast, heavy motor trucks.

In choosing the type of pavement for a road the engineer should be given a free hand. There are, however, four facts to consider—traffic, character of foundation, existing grades, and the cost, both of construction and material. This latter factor often limits the type of road to be used; but along with it the factors of facility and durability must enter in.

For country roads for both rural and motor traffic Mr. Muir suggested a double road, with a 2-in. asphalt road in the centre, and concrete side roads for country traffic.

Discussion

Mr. W. A. McLean, in discussion, said: "There was a time when we thought we knew how to build roads, with only one type of traffic to consider; but the destructive effect of narrow tires has passed into insignificance; the destructive effect from shear of the fast auto and motor truck, in which the destructive effect upon pavement increases as the square of the speed, is a new and far more serious item. Ruts appear in the road, partly as a result of this, and to obviate this evil we shall have to restrict the load as well as the speed; educate the people to 'keep out of the rut,' and build our roads wider where traffic is heavier." A lengthy discussion, indulged in by several superintendents from the different counties, followed on "ruts," with the consensus of opinion that we will have to widen our stone surface in cases of heavy traffic and educate the people that the road is theirs, and they should help preserve it by driving all over the road.

* * *

GRADING

"Grading" was discussed by Mr. A. H. Parker, B.A.Sc. The sub-grade should be brought to the proper shape and alignment before commencing to place the surface material. In Ontario, roads follow certain lines, as laid out, irrespective of the topography of the country. With the location, which is the most permanent part of the road, arbitrarily fixed, the sub-grade or foundation, as the next most permanent factor, should be carefully built. In selecting the location of a road, it should have as low gradients and as direct a route as possible. By direct route, it may not necessarily mean a straight line, a horizontal curve is often shorter than a vertical one, as over a hill.

In Ontario many of our roads have grown up from pioneer conditions and are very crooked. These should be straightened. In building new roads the centre line of the road should coincide with the centre line of the road allowance. Avoid deep cuts, if possible; they are expensive to build and easily drift full of snow in the winter. In building side-hill roads, if the centre line of the road is brought to the grade level, when the road is widened out and finished, one-half will be cut and the other half fill. This provides a minimum of labor, and therefore cost. Ordinary dirt soil will stand up with an angle of repose of 1½ horizontal to 1 vertical. The slopes should be seeded to preserve, as well as beautify, them. Drag the earth from the ditches to the centre, remove all sod, because if used it decays and leaves a soft spot. If this is unavoidable it should be allowed to dry out, then bury two or three feet below the surface. Rolling the sub-grade before the surfacing is placed is very essential; it compacts the sub-grade and shows up any weaknesses.

Drainage, perhaps, is one of the most important things in road construction and upkeep. The sub-grade should, if possible, always be built up above the high-water mark. Build the crown in an arc of a circle, and make the ditches or drains follow the general water-course, being sure that they have an outlet and are not just allowed to become an elongated pond. In grading for a road it is important to study the location, keep as low grades as possible, use sound materials, provide good drainage, and build a good foundation sub-grade.

Discussion

Mr. W. A. McLean said that in the early days it had been hard to get a good alignment in grading, but a good deal of importance was placed on it now. The old idea of statute labor in road upkeep is passing out, and an organized system of county superintendents and road engineers is taking its place. More attention is being paid to drainage and its proper outlet.

Major Sheppard, of Welland County, spoke of the effects of water-soaked foundations, and the sudden changes in climatic conditions, especially in the winter season. Rapid rising and falling of the temperature causes disintegration of the road surface. If water-soaked, frost will heave the road up, and when the weather moderates it falls back, simply breaking it up. If proper drainage were instituted half our present road troubles would be eliminated.

An interesting discussion followed on the new Ditches and Water-courses Act, its application to specific cases, and how it should be interpreted.

* * *

THE ADMINISTRATION OF A COUNTY ROAD SYSTEM

This question was discussed by Mr. G. C. Parker, B. A. Sc. The success of a county road organization depends almost entirely on the knowledge and executive ability of the superintendent. This knowledge cannot be gained in a year and for this reason it is to the advantage of the municipality that the office of superintendent be retained by the same man year after year. Referring to specific details, the speaker suggested the early spring season as the best time of obtaining an accurate knowledge of local conditions. Much information can be gained at this time regarding the necessary drainage required. It is also the proper time to have machinery repaired. Sheds can also be built during the off season—preferably at a central point—for properly housing the machines. The grader is the first machine to be taken out in the spring, and should be used on all the roads. Simultaneously the drains should be attended to. Following the grader, the roller should be placed in operation just as soon as the ground is sufficiently dried out to support the load.

Importance was also laid on the necessity of having proper specifications drawn so that there may be no misunderstanding between the superintendent and the men in charge, or with the contractor. Where roads are built by contract the superintendent should have an inspector who will see that these specifications are carried out closely. Attention was drawn to the fact that municipalities do not appear to get as good results for the same amount of money expended as a private contractor will do, and it was urged that the policies followed by contractors should be more carefully studied. The contractor watches his costs carefully, replaces a machine which continually causes trouble by a better one, sifts out his poorest teams so as not to delay the others, keeps his horses well fed and groomed, and for the most part figures according to a unit cost system, so that from day to day he can place his finger on the leaks. There is no reason why the same principle should not govern the work in municipal organization.

* * *

THE USE OF OIL AS A DUST PREVENTIVE

Mr. Huber, Assoc. Mem. Canadian Society of Civil Engineers, addressed the Congress on the subject of Dust Prevention. He first outlined the causes of dust, which include the grinding and pulverizing action due to the impact of horses' feet and vehicle tires; the shearing action of self-propelled vehicle wheels; the physical actions of rain, frost and wind; the chemical actions set up in the weathering of stone; and—usually most important of all—internal attrition, or the grinding together of contiguous stones of which the surface crust is composed. Of all these agencies only the last-mentioned is preventable.

The lecturer outlined two methods by which dust may be prevented from rising, which he classified respectively as Cure and Prevention. The first was the application of such substances to the road surface as would hold down the dust already formed. The second was the employment of such methods and material in construction that the formation of dust would be practically prevented. The first method consisted in applying various liquids such as water, salt solutions, light oils, light tars, oil and tar emulsions, all of which gave only temporary relief. The use of granulated calcium chloride was also mentioned as being feasible in very moist climates only. It was pointed out, however, that in dust prevention very much depends on the condition of the road. First-class construction is the first and greatest essential. The application of oil to a thick coat of dust affords only temporary relief, and is expensive. The lecturer outlined the various methods of applying the different kinds of oil, and pointed to the necessity of observing certain rules very carefully.

The second method of treating roadways—resulting in dust prevention—consists in covering the entire surface with a carpet coat of heavy asphaltic oil or medium-grade tar, filled with stone chips free from dust. This results in a surface from one-eighth to one-half inch thick, composed of stone chips and a bituminous binder, the object of the stone being to take the wear of traffic and of the bitumen to bind the stone together and hold it on the road. This method is more expensive than the application of oils, but is usually more economical in the end, as an application will last several times as long. The lecturer outlined the proper methods of applying this carpet coat, and emphasized the importance of following instructions carefully so that best results may be obtained. The cost of the carpet coat as described is estimated at from eight to ten cents per square yard, and the life from two to five years. Including maintenance cost, the annual charge for this road should be from two to four cents per square yard.

* * *

PAINTING AND MAINTAINING STEEL HIGHWAY BRIDGES

This subject was taken up by Mr. George Hogarth, O.L.S., Assoc. Mem. Canadian Society of Civil Engineers, Engineer of Highways for the Province of Ontario. Mr. Hogarth emphasized the importance of painting steel bridges as soon as they are erected, and of inspecting them carefully twice a year for abrasions or rust spots, which should be cleaned and repainted. He emphasized, also, the necessity of using fresh, bright steel in the erection of bridges, as where certain parts are rusted it is difficult to anticipate where the weakest spots will develop. Great emphasis was laid on the necessity of all rust, dirt and grease being thoroughly removed from the steel before the first coat of paint is applied. A new coat of paint should be given to any bridge structure every four or five years at least, not only for preservative reasons, but also on account of the improved appearance to the highway of which the bridge forms a part.

Mr. Hogarth discussed also the different classes of paint which are available at the present time for steel work, and instanced some tests made during the last ten years by the American Society for Testing Materials. These tests indicated that the best paint was composed of red lead and linseed oil, with the red lead in ample proportions. Where the bright color of this paint is considered objectionable, it may be darkened by the addition of lampblack. The speaker also warned the delegates of the necessity of watching the men carefully who had charge of the painting work. The proper cleaning of steel before the application of paint required both patience and muscle, which discouraged the average workman. It is well to pick out men of recognized skill and dependability and confine them to this particular work. The speaker illustrated his lecture with a number of samples of angle steel painted under varying conditions of cleanliness, and showed that the piece which was clean and new requires less paint, less time to apply it, and presented a much better appearance—to say nothing of the increased factor of safety and the number of years added to the life of the steel structure.

The second part of Mr. Hogarth's paper dealt with the maintenance and inspection of steel highway bridges. Many instances could be cited where inspection of a bridge has revealed a serious condition due to broken sections. For example, in many of the older structures, which were pin-connected, tension members composed of square rods with welded eyes were frequently used. Indifferent workmanship in forming the weld frequently created a weak spot which, after a few years of service, showed itself by the weld opening. Such weak points should be noted and necessary repairs made at once. Inspection should at least be semi-annual, and should result in every portion of the bridge—the handrail, the approaches, the river-channel, etc.—being brought under the careful observance of the inspector. Notice boards requiring traffic to slow down should be placed in a prominent position, and the printing kept legible. The bridge trusses should be inspected to see that they are still in line, and the chords examined for twists or deflections. The inspector should satisfy himself that all lateral bracing is taking its fair share of the stresses. All nuts should be tight and sound. The whole structure should be examined for cracks and corroding. All wooden debris that might result in fire, and so effect the bridge, should be removed to a safe distance. Careful attention should be given to the drainage of the bridge floor, and care should be taken that the drip through the drains does not strike any part of the steel work. A few dollars spent on maintenance will often prolong the life of the bridge many years, and so delay a greater capital expenditure. To this, of course, is also added additional safety to life and property.

* * *

SPECIAL PROBLEMS IN DRAINAGE

"Special Problems in Drainage," by M. A. Kemp, B.Sc. The use of tile in side drains, cross drains and approaches often facilitates the removal of water from the surface and subsoil and will render seemingly undrainable parts of the road quite dry, and will often change a very poor road into a very good one. In early roads the subject of drainage was considered a luxury rather than a necessity.

Points to consider in placing good drainage are:—

1. Follow any water-courses, and use them as outlets.

2. Keep drains open, and at the proper grade to allow water to get away rapidly.

3. Provide an outlet for every drain.

4. Use culverts, where necessary.

5. Keep the road well crowned to turn the water off.

6. Dispose of the water in small quantities.

7. In case of deep ditches, use tile drains.

Under the new Ditches and Water-courses Act all county councils must properly provide drainage for county roads. In flat districts water lingers too long in the ditches, which softens the road surface. Swamp roads, due to mud and vegetable matter, have been specially hard to maintain. Drainage in swamp roads should not be attempted without draining the whole swamp. Near to towns, to obtain the proper slope, deep ditches are often necessary. These ditches should be tile drained to eliminate danger. It is not advisable generally to drain sand roads. They should generally be left in a concave surface condition to hold the moisture as long as possible, being in a much better condition wet than dry. The usual place for tile drains is on each side of the road, with V-shaped drains from the centre to the road-side. Tiles not less than 4 ins. in diameter should be used. Clay roads need much more draining than ordinary soils. Tile drains in clay roads at first do not always give best satisfaction, but it is generally considered that this increases with age. In a properly drained road even frost will leave the road surface alone. The destructive effect of frost is directly due to the moisture contained in the road surface or subgrade. Where quicksand and soft soggy foundations are met with, they should be always tile-drained, with a good outlet if possible. If not, straw and sawdust should be placed around the drain, or even boards used to lay the drain on.

The essential feature of good roads is drainage—better drainage—the best drainage possible—and keep the drains in the best condition

Discussion

Mr. McLean: Too often the work is considered finished when a drain is laid. This should not be. They should be inspected regularly to see that they are in proper condition, and that they are doing all that is required of them. This is one of the advantages of a county road superintendent, who can continually inspect them. In heavy clay soil, where an outlet does not seem at once available, relief may often be obtained by drilling through the clay and obtaining an outlet in a gravel or sand layer below the clay bed. This is not always practicable, but is often done. In counties where there is considerable rock and stone a permanent ditch should be blasted along each side of the road by the use of machinery.

Mr. Young: A systematic upkeep of roads will be very much more easily obtained by a good system of drainage. Especially on hills, drains are found to be very satisfactory. Too much attention cannot be paid to securing proper outlets for these drains, as drainage seems to be the foundation of a good roads system.

* * *

ROAD LAWS

Mr. W. A. McLean, Mem. C. S. C. E., Deputy Minister of the Department of Highways for the Province of Ontario, with a view to interpreting to the county road superintendents more clearly the highway statutes, delivered an address on "Road Laws"; the legislation under which the Provincial Government extends aid to municipalities for road improvements and the statutes upon which municipal organization for road purposes is based, should be clearly understood by all road superintendents and highway engineers. Road laws have been simply a matter of evolution; as requirements demanded they have been amended and revised to fit the condition of existing affairs. One of the first statutes passed in Ontario legislation, in 1793, was that respecting statute labor on roads. This is an old system, having been used in the United States and Great Britain. It has done a lot of good, can still under good organization do a lot of good, but it is giving place to a system for good roads, properly organized and maintained, by municipalities with the aid of the Government.

Roads should be constructed according to the traffic to be carried over them, should be paid for according to construction, and assessments made in proportion to the benefit derived.

There are three general sub-divisions of roads—main highways, market roads and township roads. Along the main highways, which extend from towns to cities, in the earlier pioneer days the settlers built their homes and farms. One of these main highways is the old road from Detroit, through Windsor, Chatham, Woodstock, Ingersoll, Brantford, Hamilton, Toronto, Belleville, Kingston, Prescott, etc., to Montreal, and along this old highway or within twelve miles of it is half the population of Ontario. At right angles to these roads are the market roads, which are essentially the heart lines of the municipality. From these market roads branch off the township lines. These latter roads carry very little traffic. The main roads, comprising only 18 per cent. of the total roads, carry 78 per cent. of the total traffic.

It is planned to place the main and market roads under a separate organization and to institute a good maintenance system. Small farm side roads will still be left in the hands of the township authorities. The counties will be expected to take over the market roads and the main roads and will be encouraged to improve and maintain them. There are some main roads, such as the Toronto-Hamilton Highway, which will be placed under separate control.

The principle that cities shall pay their share in the cost of highway construction and maintenance ought to be inaugurated. Unfortunately, when a city is incorporated it is isolated from the county, as a separate unit, and is not assessed by the county. In the United States and Great Britain this is not the case. There they remain in the county and are assessed for a county tax. The result is that in paying for concrete highways the cities, which use them to a great extent, pay as high as 85 per cent. of the cost of construction. In Ontario this is not so. Some means has to be arrived at whereby the cities shall pay their just share.

The plan proposed is to adopt a suburban area around the cities. The roads in these suburban areas will be county roads constructed by the county. The city council will appoint a commissioner and the county council one, and they in turn select a third. Their first duty is to study the situation with respect to how far out on the highway the city shall pay for construction and maintenance and to determine the expenditure or first cost and maintenance. When this report is received and amended and adopted, both city and county subscribe equally. That is, as a county road the Provincial Government grants 40 per cent., the city and county each then paying 30 per cent. of the cost—with a provision that the tax on the city shall not exceed one-half mill in any one year. This provision in a way determines the mileage to be constructed per year.

This in general constitutes the features of the Ontario Highways Act, passed last session. It also provides for main roads, however. The province pays 20 per cent. of the maintenance cost of county roads. Also, where any township provides a permanent overseer, the province pays 25 per cent. of his salary for the first three years. The department is urging the township to employ such men. He should be as essential to the township as the clerk. This time will come, but the public will have to be educated to it.

All the statutes on roads and road laws have been compiled in a separate volume for the convenient use of the superintendents and engineers. The difficulty of getting laws made to cover what is wanted, and nothing more, is very evident.

The department especially desire that the road superintendents and engineers in compiling their reports for the department will make them as clear, concise and accurate as possible. In last session's sitting we had an amendment to the Highways Act passed which gives county superintendents power to act practically as owners of the highways.

Discussion

Mr. Bowman: "Our congratulations are due Mr. McLean for the splendid work he has done. We are pleased to know that he has been gazetted as Deputy Minister to the new Highways Branch. We have now a very good system of road laws, and all counties should take hold and make themselves available of the Government Grant." Mr. Bowman spoke on the new suburban roads and stated that they were trying to avail themselves of the new law to lay a concrete road from Galt to Preston.

Mr. Fair suggested having each farmer looking after his own section of road and promoting competition to secure best results.

The subject of "farm approaches" drew forth a lot of discussion as to who should put them in. It was generally agreed that the municipality should take care of everything between two fences—put in approaches and charge the farmer with them. If left to the farmer he does not always understand the business properly and is apt to do poor work.

The question of having the city pay some share in the maintenance was also fully discussed. It was felt that the city, either directly or indirectly, profited by the highways, and as representing a large population located at some point on it, they should in some way contribute.

Mr. Fair suggested placing the auto fees in a separate fund for special work. Mr. McLean stated, however, that the auto department is to be incorporated in the Highways Department and the fees will go directly to the road. The Toronto-Hamilton Highway was the next subject. The province is only paying 25 per cent. of this road, which is not so much as it pays for county road construction.

Mr. Talbot introduced a discussion on the division of repair and construction of roads and the Government subsidy in each case. In the case of repair the Government pays 20 per cent., in new construction 40 per cent. Mr. Talbot spoke of the trouble in discriminating between these, and thought that an average of 33 1/3 per cent. would be better. Mr. McLean, however, considered while it would be hard to draw a hard and fast line between them, he didn't think it would give any considerable trouble if the law were judiciously administered.

Closing Roads Under Repair

Mr. Russ introduced the question of closing roads to traffic while under construction or repair. While the superintendents have no real power to do so they should use their good judgment in regard to eliminating trouble from damages during repair.

Mr. Anderson: The subject is one not very clearly defined by the statutes, and we ought to have some protection for ourselves while the construction machinery is on the road.

* * *

BITUMINOUS ROAD CONSTRUCTION

There is a growing tendency in Ontario towards the use of bituminous roads—that is, roads in which tar, asphalt or asphaltic oils are used as a binder for stone, gravel, sand and slag—or as a protective coating in forming the wearing surface. Mr. Muir, in his paper on "Bituminous Road Construction," dealt with the special features of a number of types of bituminous construction. In recent years the advent of the automobile and heavy traffic has evolved new types of road construction.

Methods of using bituminous materials may be classified as follows: (1) Penetration method; (2) Mixing method; (3) Carpet coats. In the first method broken stone passing a 2 1/3 in. ring and retained by a 1½ in. ring is spread evenly over the ground about 4 inches thick and rolled to an even surface. Into this heated bitumen is poured in best manner available, using about 1¾ gals. of bitumen per square yard. Over this a light layer of stone chips is spread, and the surface thoroughly consolidated by a steam roller. There are a number of methods for pouring or placing the bitumen on for this process—hand sprinkling, gravity sprinkling and pressure sprinkling. For best results the bituminous material should be heated to properly penetrate the surface.

The second method is a surface made by the mixing method, and called "asphaltic concrete." This system is well adapted for improving old macadam roads; it is more expensive than the penetration method, but is also more durable and desirable, and will support heavier traffic. Over a layer of broken stone is first sprinkled a light coat of tar as a binder coat to unite the surface to the foundation. On this is spread a layer of stone with which hot asphalt or tar has been previously mixed, generally in a plant on the roadside, in about the proportion of 15 gals. tar to 1 cu. yd. of stone. This coat is spread and rolled to a depth of 2 to 3 inches, then treated with a layer of stone chips to dry the surface and again rolled. The materials should be uniformly proportioned, using the various sizes of fine stuff, sand, stone and bitumen in carefully and evenly graded quantities. The asphalt or tar should be heated to a uniform temperature, care being taken that it is not over-heated.

In the third method the "carpet coat," as the name implies, consists of a thin layer of asphaltic materials spread over the surface of a broken stone road. Asphaltic oil, a fluxed asphalt, or a suitably fluxed tar are the materials generally used. The road surface, before application, for best results, should be smooth, free from ruts or holes, and thoroughly cleaned to allow maximum adhesion. If the oil used is very heavy and contains a high percentage of bitumen it is best to coat it with stone chips or pea gravel to prevent stickiness and give a better wearing quality to the coat. This construction protects the surface of the road from wear and effectively prevents dust.

Discussion

Bituminous construction has up to the present been more especially adopted in the vicinity of Toronto but is now becoming more popular in other vicinities. In Waterloo, according to Mr. Bowman, on certain heavily travelled roads, the tendency is towards concrete roads or concrete subsurface, with a bituminous surface coat. Mr. Bowman also thinks that for highways near towns or cities, with heavy traffic, waterbound macadam has served its day. The future roads have got to be cheap and easily maintained. In this respect concrete, while it has a high initial cost, costs practically nothing for maintenance.

* * *

CARE OF EARTH ROADS AND USE OF LOG DRAG

Due to the fact that eighty per cent. of our country roads are dirt roads, the great necessity of keeping them properly maintained is very essential. Mr. W. H. Losee, B.Sc., in a paper on "The Care of Earth Roads and the Use of the Log Drag," pointed out the good results that can be obtained by the systematic use of the drag on earth roads.

The grade, or crown, of the road depends a great deal on the character of the soil. If it is heavy clay the crown should be relatively high; if sand, it should even be inverted to retain the moisture. But in all roads except sand, they should be crowned and adequately drained. Clay roads may be improved by the use of sand, and vice versa, by a thorough mixing of the materials and dragging to a good crown.

Great care should, however, be exercised in the time of dragging. The best time is generally immediately after a rain, when the earth will work well, yet not cake. Clay should be fairly sloppy, to prevent sticking. Or again, in real dry weather just before a rain the soil is easily placed wherever required. Good results can be obtained by dragging as early in the spring as possible, and again, as near as possible before the frost sets in. Dragging should be done systematically, never trying to increase the mileage at the expense of the quality of the work. Organize the farmers to do their own section and stimulate competition for best results.

Discussion

An exchange of ideas and methods used in dragging in the different counties followed. General opinion was that it produces the best of results, but is not sufficiently used in the townships. New roads are often necessary because of the neglect to properly grade and maintain earth roads to make them passable the year round. The relative merits of the split log and the steel drag were also discussed. The steel drag may accomplish more work but it requires ever so much more power and in general is rather more cumbersome to handle—wonderful results can be accomplished by the systematic use of a light split log drag on earth roads.

Good Roads as Monuments

During the Thursday morning session Mr. G. S. Hendry, secretary of the Ontario Good Roads Association, and Mr. K. W. McKay, expressed views in regard to organizing and establishing a monument to our returned soldiers, in the way of an improved system of highways in Ontario. Their idea was to employ returned soldiers on highway improvement and in so doing to improve both the soldiers' conditions and those of the province; to designate such improved highways by names now before the world's eye, in commemoration of the work done by our Canadian soldiers.

* * *

STONE FOR VARIOUS KINDS OF ROADS

With the rapid developments in highway engineering the growing demand for permanent construction, and the increasing severity in conditions that our roads are required to withstand, a careful choice of materials is demanded. The careful selection of materials is of equal importance to careful methods of construction if best results are to be obtained. This was pointed out by Mr. G. C. Parker, in his paper on "Stone for Various Types of Roads."

The foundation of the road is required to withstand the weight of the traffic and the action of the frost, while the top or surface coat is required to meet more severe and more varied conditions. Wear is caused by abrasion of steel tires on a smooth surface and impact on an uneven surface, impact of horses' feet cause a dislodgement of stones or breaks them, while the dislodgement of stones and the effect of shear by auto traffic is serious. During dry weather the rubber tire flattens out as it comes in contact with the road surface and on leaving it picks up the dry binder from between the stones and the strong current of air, ever present under a swiftly moving vehicle, carries it away in the form of dust. In order to efficiently resist these effects the stone or rock must be tough and the binder sufficiently strong so that the road will not go to pieces quickly.

If the road becomes impregnated with water the stone, as well as the binder, absorbs an amount of water and if frost falls it must be exceedingly tough to withstand the frost action. The binder is more elastic and is not so subject to frost. Trap rock and limestone are the most universally used stone in Ontario, the latter being the more so.

That the probable behavior of a road material on the road can be largely determined, tests of its physical properties are being watched more fully every day. In testing stone the following properties are determined: wearing qualities, toughness, cementing value, absorption and specific gravity. These tests have been conducted under the direction of Mr. McLean and the equipment and methods used are almost identical with those at Washington, D. C. The apparatus was here shown on the screen and explained.

The power of withstanding the destructive agency of climatic conditions is an essential factor in the choice of stone to be used. Some rocks might give good results in all the laboratory tests, but not be able to withstand the weathering action. This is an important point in choosing surface material and can only be decided by experience often. The size of the stone and relation to the voids is another essential condition. Some engineers specify one size and some another, but the general size adopted is 2 in. stone, that is, stone passing a 2½ in. circular opening and retained by a 1½ in. opening; such stone to have good binding qualities, key well, and leave as small a per cent. of voids as possible. The stone should carry the load, the cementing material being present only as a binder.

Discussion

In reviewing the paper Mr. McLean pointed out the importance of it to the superintendents of the different counties. Most counties have their own stone; a few have to import it. It would therefore be wise for the superintendents and engineers to know something of the stone they are using, or are contemplating buying. In concrete work, too much stress cannot be placed on the importance of testing sand and bank-run gravel in concrete work. Numerous failures can be traced to poor grades of sand being used. Engineers found the item of cost a big factor in choosing the stone. Supplies may often be had near the site of proposed work, which were not so good as samples miles away, but the item of cost and earlier renewal favored the closer quarry. The binding qualities of stone from several different quarries formed the basis of a good discussion. In general the first cost only comes once, while maintenance is, or should be, always with you; it would pay, therefore, to use a good quality of material, probably slightly increase first cost, but considerably reduce the maintenance cost.

Mr. J. F. Whitman, engineer in charge of trunk line construction in Northern Ontario, gave a brief talk on the rock and methods used in building and maintaining roads in Northern Ontario around Sault Ste. Marie.

* * *

TORONTO-HAMILTON HIGHWAY

"Construction Methods on the Toronto-Hamilton Highway," by Mr. H. S. Van Scoyoc, chief engineer Toronto-Hamilton Highway Commission, was an illustrated lecture, both by slides and moving pictures, on the methods of handling and placing the materials on this large piece of construction work which is of such great interest to all road builders and engineers. A full description of this work appeared in the Contract Record of January 5. After the talk Mr. Van Scoyoc answered numerous questions put to him by various superintendents.

On this work, all materials, both sand and stone, were inspected in the pits and quarries before being shipped to site. Sand strong in quartz and silicate was desired, but most sand in that locality was limestone. No gravel was used, as it was not commercially feasible as compared with broken stone and sand. All cement was required to be in the mixer at least 45 seconds. The maximum advance was 630 feet in twelve hours with an average of 420 feet in ten hours.

* * *

THE CARE AND OPERATION OF QUARRYING AND CRUSHING EQUIPMENT

Mr. R. M. Smith, B.Sc., dealt with the care of modern portable quarrying and crushing outfits and the manufacture of road material for county roads.

The first operation in opening a new quarry is the stripping. This factor varies with the nature of the site, and is often eliminated where the rock is exposed, but as a rule costs about 25 to 30 cents per cubic yard to remove. Always some surface material should be removed, even if it is stone, because better quality always exists lower down. With the stone exposed the machinery may be erected. Crushers are either jaw or gyratory type, the former being most used in Ontario. The location of the crusher is one of the fundamental factors in efficient operation. If the crusher can be placed below the quarry face, the material can be transported by gravity and dumped into the hopper, thus eliminating extra handling, which, in the case of a large quarry, would be no small item. Always work down hill, never up, if it can be avoided. It is well to emphasize setting the crusher on timbers, making it absolutely rigid. A crusher allowed to operate standing on the wheels is being hurried to the scrap heap.

The shape, size, and composition of the crusher jaws are the chief factors to consider in a good crusher. Manganese jaws are preferable—they cost much more than ordinary jaws, but they will outwear several sets of the latter, and require practically no attention. Jaws approximately 12 x 16 to 10 x 18 have been considered the correct size.

From the crusher, stone is carried to screens by bucket elevators. These screens demand consideration and attention. For limestone they contain two sizes, 1¼ in. and 3 in., and for trap rock are somewhat smaller, approximately 1 in. and 2½ in. The storage bin should have ample capacity with traps for loading stone into wagons. Often stone in a limestone quarry can be removed with little or no blasting; then the rock becoming firmer requires powder or dynamite to remove it. Drilling may be done by hand, steam or compressed air, with the former two the most common, but being slowly replaced by the latter. The cost per foot of hole drilled by the hand method is 35 to 45 cents and by mechanical means 15 to 20 cents for 1⅛ in. and 1¼ in. drills.

Mechanical drills should be operated by capable men—experience means efficiency. Great attention should be paid in steam drilling to the apparatus. In setting a drill great care should be taken to level the rock so that the steel will strike square. When starting a hole, short light blows should be used, the strokes being gradually increased. Drills should be changed approximately every 15 ins., depending on the hardness of the rock. The operating pressure on the drills in the mechanical process is approximately

80 to 90 lbs. per square inch. Steam or air is not only cheaper than hand but saves considerable man power, and work is carried on at a faster rate. The explosive used to break the rock which seems to give the most satisfaction is gunpowder or low freezing dynamite. A mild explosive causes fewer small fractures and therefore prolongs the life of the road.

Stone is generally moved from the quarry face to the crusher either by dump cart, hoist or the old fashioned wheelbarrow. The hoist is probably the most efficient, but in most portable outfits this does not exist, and dump carts or wagons take its place. Of the latter two the dump cart is certainly to be preferred. One horse will do the work of a team. Two or three dump carts at most can keep a crusher busy; they are handy to handle in the quarry, quick to unload, no time being lost at the crusher platform, and generally more efficient than any other method of moving material, except probably in the case of the gravity methods, previously explained. The crusher should be run to full capacity at all times; the efficiency of the outfit and the speed of road building depend upon the crusher, which, as a result, demands the greatest attention.

In some counties large quantities of field stone and gravel exist, which, when crushed, make a very good road material, the only objection being its lack of uniformity. The life of a quarrying and crushing outfit depends partly on the local conditions, but principally on the kind of material it has to handle. Regardless of the kind of material, a crusher will depreciate rapidly if not properly handled; good management will practically double its life.

Discussion

Mr. Talbot and Mr. Fair described their respective outfits, illustrating with interesting lantern slides.

Mr. McLean in reviewing: Some counties have an efficient supply of stone, but do not use the crusher as much as they should. If the counties would use larger crushers they would be able to get satisfactory financial returns out of the stone, the trouble often being that they use too small a crusher. Speed in road construction depends on keeping the crusher going. Keep it in good repair, even at the expense of keeping the engineer after hours to fix it up.

Mr. Wilson described the outfits used in Halton County, and gave some figures on cost and output. The discussion pointed towards lower cost by contracting the quarries than operating them.

Major Sheppard was of the opinion that the personnel of the foremen had a great deal to do with the daily output, records showing that one man would double the output of another from the same quarry.

Mr. Fair: The variation in the work of manufacture of road material demands a man of good insight, and well able to handle men. Such a man, if he can be got, should be paid such wages as will keep him permanently.

Mr. Sheppard: What do you consider good pay for a foreman?

Mr. Fair: $3.50.

Mr. McClure wanted to know the relative merits in size of openings and length of jaws. Finds a tendency for some stone to fly out of the crusher.

Mr. Smith: The common sizes are 12 x 16 and 10 x 18, the former being the most common.

Mr. Anderson, of Lennox and Addington, who has had considerable experience, places extreme importance on the shape of the jaws, using a jaw somewhat concave so it would grip the stone on closing. Some discussion followed on crushing field stone and the cost of opening quarries. In Prince Edward, according to Mr. Cleminson, due to depth of rock below surface, it costs approximately $300 to open a quarry.

RESURFACING GRAVEL AND STONE ROADS

Mr. A. S. Smith, in his paper on "Resurfacing Gravel and Stone Roads," gave various methods which may be used, each dependent on the degree of wear which the surface has attained. Gravel comprises 75 per cent. of the improved new road construction. In designing a new road, the nature and extent of the traffic must be known; these are determining factors in the width and depth of the construction. Another important factor is the proximity of material—which is the most economical to use.

In early gravel road construction it was customary to dump on any kind of gravel, of any size available, and leave it to take care of itself. It was not rolled, and soon rutted; being soft, it absorbed a large amount of water, and was invariably in time forced out, to the extent of at least 25 per cent., into the ditch. Now, with the advance of knowledge in this respect, it could be done properly. When resurfacing, it is also a good time to correct defective grades, and place permanent culverts.

The proper method of resurfacing is to clean the road surface of foreign matter, break up the surface to a predetermined depth by the use of spikes in the roller, or by a scarifier, bring to proper crown by the use of the grader, add new material, and carefully consolidate with the roller. The use of the scarifier or spikes effects a very good bond between new and old materials. Clean sharp pit gravel should be used, 60 per cent. of which will pass a ⅛-inch screen. Round beach, pebble gravel should not be used, because of its low binding qualities. Great care should be given to rolling, starting at the sides, and working to the centre. Work from the pit away in order that traffic may help consolidate the surface.

In resurfacing stone roads the nature of the traffic will again determine the type of the material for resurfacing, the extent of the thickness of the coat and the size of the stone. For heavy traffic, hard, tough stone with good weather-resisting qualities, from 1½ to 3 inches, is the best size. Loosen the old surface, grade, and add new stone in coats, rolling each coat well. When the top coat is so consolidated that the stone does not move under the roller, apply the dust coat and water, in proper proportions, and roll into the voids. Brooms can be used to good effect. Another method is to clean the old road, fill the ruts first, then place the stone in the same manner, the difference being that the scarifier is not used to effect the bond.

In dry weather, water-bound macadam is apt to be dusty—traffic loosening the dust—which blows away, leaving the stone exposed. This can be greatly remedied by the application of oils or tars.

Discussion

Mr. McLean: In some counties, construction is the important item; in others, reconstruction. Some counties have been favored with plenty of material and have made good progress in highway improvement. Others, less fortunate, have stood still.

Mr. Fair, of Frontenac, did not consider the use of the scarifier good policy. In Frontenac the majority of roads are old stone roads—some very old, with comparatively good foundations—and it was not considered wise to destroy such foundation by the use of the scarifier. Good bonding results were obtained by filling into and placing a new coat. Material for resurfacing is very plentiful in Frontenac; in one case a mile and a quarter of stone road was resurfaced 10 to 14 inches thick. The scarifier, however, was used to good effect on hills, and side ditches, in repairing them.

Mr. Russ advocated the use of the roller with short spikes, which, while it did not disturb the foundation, broke up the surface sufficiently to effect a good bond.

Mr. Wheelock, of Orangeville, said the trouble is roads do not wear even, and it is very difficult to get a good bond. Thinks the use of the scarifier gives good results. He also asked the opinion of the conference on the use of clay with gravel as a binder, his own experience being that in wet weather it was muddy, and in dry it dusted and flew away. This seemed to be the consensus of opinion.

Mr. McLean: If only going to repair the road by adding a 2-in. or 3-in. coat, break up the surface, but if 7 ins. or 8 ins. is to be added, do not disturb it.

* * *

CONCRETE BRIDGES

"Concrete Bridges, Culverts and Floors," by Mr. Arthur Sedgwick. Efficient construction will effect a great saving in the cost of all concrete work. The adaptability of concrete to the construction of culverts and short-span bridges is due to its permanency, simplicity of construction, and general availability and reasonableness of cost. Portland cement concrete is probably the most durable building material known to-day, a condition which is only realized, however, if the aggregates are properly mixed and the structure properly designed and constructed. Ignorance and lack of experience in the past has led to bridges only lasting a portion of the time they were normally capable of. This condition ought not to exist to-day; mechanical skill of a high order is not necessary to design or construct a concrete structure, the form work is not difficult, neither are the precautions in mixing or laying the concrete. Yet unless the work is carried out under men experienced in it the results are often jeopardized.

The time has arrived in Ontario when we should expect our local public works to be constructed with a neater and more finished appearance. In cities and towns works are usually built to show a degree of refinement and finished design. This should be equally true of highway structures. The causes for poor outward appearance of so many of our bridges generally are: (1) lack of sympathy on the part of the community for something better; (2) failure on the part of the engineer or road superintendent to enforce the specifications; (3) lack of efficient inspection; (4) incompetence on the part of the contractor or foreman. Some of the common defects in country structures are: the structure is placed off the centre line of the road, or not in line with it, broken corners and edges, distorted walls due to forms being loosely built and insecurely braced, trying to improve porous surfaces by the injudicious use of plaster. In addition to these unsightly effects, the following defects in methods and results which lead to a materially weakened structure as well as an unsightly one: the injudicious use of pit gravel, insufficient and poorly mixed cement, poorly supported forms, which allow the concrete to settle in setting and misplacement of steel reinforcement. To avoid these defects, a brilliant mind is not necessary, but they do require attention by a thoroughly experienced and common-sense foreman.

Wherever possible the forms should all be built and braced before laying any concrete. Many culverts and some bridges are spoiled or endangered by not having the foundation footings carried down deep enough. In sandy soils particularly, there is a danger of water undermining the structure. In spite of these the construction of a culvert should be an easy matter. In point of efficiency the built-on-the-field culvert is far superior to the ready-made variety. As compared to the circular section, a square or rectangular section has relatively higher water-carrying capacity at any height of water.

With the advent of the new and increased traffic, culverts and bridges should be built wide enough to accommodate future development. Small culverts up to six or eight feet in diameter should be built to allow for not less than a 24-ft. roadway. The increasing occurrence of accidents from motors colliding with handrails on narrow culverts makes it essential that in future they be built to the width mentioned.

The present practice of placing floors in steel highway bridges is to lay the stringers on top of the floor beams, uniting them lightly to the top flange; placing the concrete floor slab on these and relying on them to hold the stringers together and prevent toppling due to lateral forces and vibrations. The increased use of the motor truck will necessarily put much severer strains on the bridges and for future construction it is considered advisable to rivet the stringers to the webs of the floor-beams as is done in railway and building construction; also to extend the concrete floor half an inch below the top flange of the stringers in order to stiffen them against lateral deflection and movement.

Mr. Sedgewick pointed out, by the use of slides, some examples of different defects and results of defective construction, besides showing a number of interesting views of concrete bridges and culverts.

Discussion

Mr. Bleaker: We are having trouble with our concrete floors rutting. What is the cause, and how can they be remedied? One bridge is 300 feet long, has heavy narrow tire traffic, and has been down five years.

Mr. Sedgwick: If it has rutted in five years, it was poor concrete.

Mr. Connor: It is just a question, if it has rutted, whether it should not all come off and be resurfaced; it is apt to break through any time. I have patched concrete floor ruts by the use of a rich cement plaster with a mixture of iron filings to give it good building qualities.

Mr. McLean: Have you had any experience with creosoted wood blocks? It might be resurfaced with them without increasing the load on the bridge enough to render it unsafe.

Mr. Wheelock: We find the use of creosoted wood block on creosoted planks and stringers very expensive, an 18-ft. by 70-ft. bridge costing $1,400. It may give a good long wearing surface if properly sanded, but it does not increase the strength of the floor. If a floor ruts, take it up and resurface it—it is the best way and probably the cheapest.

Mr. Talbot described some experiences on placing concrete, in both excessively hot and cold weather. In one case the concrete became baked before setting, and under traffic ground out. Concrete can be laid in the coldest of weather if not allowed to alternate between high and low temperatures, which disintegrates it.

Mr. Connor pointed out the necessity of the proper placing of reinforcing steel in concrete. The proportion of the depth of the reinforcement to the depth of the member has a definite bearing on the strength of the structure.

THE OPERATION AND CARE OF THE ROAD ROLLER

This topic was covered by Mr. W. Huber, Assoc. Mem. Can. Soc. C. E.: The quality and amount of work produced by a road-building outfit depends on the efficiency with which the roller is operated. While the introduction of the grader and rock crusher have reduced the time and cost of road construction, it cannot be said that they have greatly raised the quality of the work on macadam roads above that as practised by McAdam. It remained for the self-propelled road rollers to accomplish this. Just to what extent the quality of the finished road will be improved depends largely on the manner in which the roller is operated.

To secure a properly crowned surface of crushed stone so compacted that further consolidation by traffic is impossible, a surface bound with stone dust or screenings filling all interstices so as to prevent movement of the stone, and the whole cemented together in a solid mass capable of distributing the weight of traffic over considerable area of sub-grade—it is necessary to consider methods of securing a maximum consolidation of stone with the least expenditure of time and labor.

It must not be expected that satisfactory consolidation can be expected where the sub-grade is not itself solid. Consolidation by a roller is due to its weight alone—high speed is detrimental due to the thrust of the roller. To secure rapid consolidation the stone at the side should be confined to prevent spreading.

Never roll too thick a layer at once; better results are got by doing it in thinner layers more often. Always commence rolling at the side and gradually work towards the centre; by rolling the sides first side movement is prevented and the crown maintained.

Rolling should continue until the stone under the roller shows no movement. Consolidation may be hastened by a light sprinkling of water. Best results will be obtained in rolling the road in sections of definite length, being sure to thoroughly finish one section before moving on. When the stone has been thoroughly consolidated, and not till then, the screenings may be applied. The application of screenings is almost an art, and has much to do with the success of the roadbed. Thoroughly wet the screenings before rolling of the binder coat is commenced.

On his skill and attention to details by the operator depends the success of the finished road. He should be a man of intelligence and good judgment, and a student of his work, for his greatest source of knowledge will be his own experience:

Discussion

Mr. McLean: County superintendents will save themselves a great deal of trouble by properly educating the roller operator, in whose hands rests the success or failure of the road.

Mr. Wilson stated that enough attention has not been paid to rolling. He gave a description of rolling operations in his own county of Halton.

A lively discussion took place on the relative merits of steam and gas rollers. The gas roller, if properly operated and maintained, claims distinctive advantages over the steam roller—the necessity of getting up steam in the morning, stopping for fuel and water, etc., are overcome; but it was felt that the average operator did not as yet know enough about gas engines to operate them properly.

MAPS AND PLANS

"Maps and Plans," by Mr. T. M. DeBlois, S. B., Assoc. Mem. Can. Soc. C. E. Good maps are necessary to systematic road development. The Department is constantly preparing maps of counties and townships, copies of which are available for the use of county road superintendents and engineers. They are a source of information on county roads, which can be easily and quickly referred to for information. It is proposed to have a standard legend for the different constructions, kinds of roads, bridges, culverts, gravel pits, and quarries, all marked on the map. The superintendents are urged to co-operate with the Department in the use of maps, in correcting errors, and notifying the Department of any changes made. They should be of special use to the superintendents in studying the profile of county roads, in determining the amount of cut and fill necessary in building a proposed road, estimating the grades, and from these the cost of the construction.

Discussion

Mr. McLean pointed out the necessity of co-operation between the superintendents and the Department in the use of maps. He also considered a course of instruction in the use of field instruments would be very beneficial to the superintendents in affording them a better knowledge of road profiles and drainage slopes, and in aiding them in laying out new roads. Mr. Wheelock agreed with Mr. McLean in regard to the use of instruments and the aid of maps and plans in studying a location for estimates before starting the construction of a road.

Mr. McLean, in reviewing the conference, and the subjects discussed, asked the members to notify his department if there was any problem or subject they would like discussed next year. At present about half of the counties were working under the provisions of the Act, and it is expected that before long all counties would be included. The Department have tried to make the papers as practical as possible, but it is often hard to discriminate between theoretical and practical. The theory of to-day will be the practice of tomorrow.

Mr. Fair requested a paper on Sand Clay Roads and the cheapest and best means of improving sand roads.

Mr. Talbot suggested a discussion on the working of the Compensation Act in regard to the municipalities.

Mr. Elison—With the increased traffic on country roads something has got to be done with country bridges. Would like to see the Department send out engineers to inspect all bridges, and where necessary have new ones built.

Mr. McClure would like to hear something about snow fences, and the law in regard to placing them.

Mr. Young, on behalf of the superintendents present, moved a vote of thanks to Mr. McLean and his staff for the splendid work they have done in assist-

The Kaministiquia Power Company

Rapid development of Canadian Twin Cities Due Largely to Ample Supply of Dependable Power — Latest Installation Work at Kakabeka Falls

By P. R. Farrow*

Penstock Gates

Two heavy wooden flap gates, built of 10 in. x 10 in. timbers, having proved unsatisfactory owing to their great weight and difficulty in handling, a set of five steel gates, with 10-ft. diameter openings, were installed in front of the bellmouths leading to each penstock, each of which supplies its own generating unit with water through an iron pipe.

These gates, with their operating mechanism, weigh just over twenty tons each, and were supplied by Messrs. J. M. Voith, and erected under the supervision of their mechanic. The heaviest part of the shipment weighed 7½ tons and consisted of the 10-ft. diameter gate, which was shipped in one piece. The outer casing, in four parts, was bolted together in place and concreted solidly into the walls of the building and fastened with bolts into the vertical wall. Owing to the outbreak of the European war the operating mechanism was not received and temporary expedients have been adopted to open and close the gates.

It was the intention that the gates when normally open might be closed by an operator in the power house pressing a button or by an excessive increase in the velocity of water in the penstock. A storage battery placed near the forebay, in a specially designed house, supplies current to an electric motor mechanically connected to each gate. Switching equipment automatically starts the motor for closing the gate only when required; a clutch and a handwheel serves to open the gates. An attendant is necessary to fill the pipes in order to provide against over rapid filling for the penstocks.

* Power House Superintendent.

Penstock No. 4

The dimensions of this steel pipe are: length 740 feet, diameter 11 ft., thickness of top plates ⅜ in., thickness of bottom plates 13/16 in. Two 7 ft. 6 in. diameter bellmouth pipes from the forebay wall, feed into the common 11 ft. diameter pipe about 60 ft. from the forebay. The pipe then slopes at 23 degrees for 250 feet and changes to a slope of 9 degrees for 125 ft. and then forms a curve on a 262-ft. radius, 365 feet long, with large concrete bulkheads at each end to prevent movement. A sharp slope and a bend brings it to a nine-foot diameter butterfly valve which terminates the penstock. A drain discharges the water into the power house tail race, when it becomes necessary to empty the pipe. The joints in the steel work consist of double riveted lap joints near the forebay, gradually changing to triple-riveted butt joints at the power house.

From the forebay to the commencement of the curve the pipe is carried on concrete saddles placed about 25 feet apart and two feet wide. Around the curve steel saddles are used, resting upon a steel base so that expansion or contraction may be absorbed by changes in the length of the curve.

Cover.—Over the penstock a concrete cover has been built with a clearance of 18 ins. between the pipe and steel work. Angle iron ribs, curved to radius and projecting into a light concrete wall foundation are spaced three feet apart by iron bars punched and riveted to them. These bars in turn serve to hold poultry netting and tar paper which forms a backing for the 1½-in. thick concrete cover-

Interior of Power House showing 2 exciters, 3-5,000 h.p. direct connected units, and new 12,500 h.p. unit in background—Operating room to left, transformer gallery in foreground.

General View of the Kaministiquia Power Company's Hydro-electric Station at Kakabeka Falls Shows Forebay and Spillway

ing, which was reinforced with triangle mesh wire. The covering was placed by a cement gun to the required thickness and is of the usual 1:2:4 mixture. It serves to protect the iron pipe against excessive temperature changes, and prevents the water on the interior freezing in winter time.

Doors are provided in the side so that inspection may be made at proper intervals to prevent rusting.

Messrs. John Inglis Company, of Toronto, provided and erected the penstock. All excavation and concrete work in connection with erecting saddles, bulkheads and foundations was done by the company. Shop and field inspection of the steel work was in the hands of the R. W. Hunt Inspection Company, of Montreal.

Valve House

Over the butterfly valve at the lower termination of the penstock, a concrete building with drains was constructed, the floor of which has been made into a workshop for repairs to machinery, etc. A small lathe and emery grinder and an electric drill have been furnished. This building has a concrete saw tooth roof, in two spans, which gives good lighting, although the building is on the north side of the power house proper, and lies so low that wall lighting is practically impossible. Light is also admitted to

Forebay and Penstocks—No. 4, to left, 740 ft. long, 11 ft. diameter.

:ks, Reinforced Concrete Power House and Tail Race—Kaministiquia River in Foreground and Transmission Line to the Right.

the power house from this building, through clear glass windows. In this same building is a water motor with gearing for operating the large butterfly valve of the penstock and turbine. It is reversible and controlled by hand wheels in the power house. The water supply to drive this motor is obtained from an independent source, making the whole installation reliable for use in emergency. The joint between the butterfly valve and turbine inlet pipe is a special type consisting of a groove on the interior of the pipe into which ½-in. lead packing is caulked. Short steel fillers on the outside, against which the flange bolts are drawn tight, leaves the lead to be forced into all small openings by the pressure of the water on the interior side and will also allow the large valve to be removed in the future, should any repairs become necessary.

Turbine

This unit, supplied by Messrs. J. M. Voith, is a twin spiral, inward flow, Francis type wheel with a maximum B.h.p. of 12,500. The supply pipe from the 9-ft. diameter inlet valve is a tapered steel pipe embedded in concrete and is furnished with a drain to take away leakage from the inlet valve, and empty the turbine when the latter is closed down. Water is distributed around the two cast iron wheel cases, with arm inspection covers, through balanced steel gates, the openings through the same being adjusted by the governor in accordance with the load on the unit. From the gates it passes to enamelled bronze runners attached to the steel shaft, which is directly coupled at one end of the generating unit. The water then discharges into a central pipe or draft tube gradually increasing in size until it reaches the tailrace. This draft tube is steel for seven feet and then concrete to the outlet and is curved to discharge the water horizontally. It is seven feet in diameter at the point of discharge from the turbine, and is rectangular in form at the point of discharge, being nine by sixteen feet. The surface was carefully smoothed to obtain proper discharge with a maximum efficiency in the turbine.

A relief valve 5 feet in diameter serves to discharge the water when the load is suddenly thrown off the unit, and prevents excessive rise in pressure in the penstock, or water hammer. This valve is kept closed normally by oil pressure from the governor pump, but open by means of a piston valve, which relieves the pressure when the governor gates close rapidly. The time and distance of opening and closing are capable of adjustment by means of dash-pots.

The governor is of the fly-ball and relay type, operated by oil pressure from a belt-driven rotary pump, at a pressure of 280 lbs. per square inch. It serves, by means of mechanical connections to a cylinder and piston, to keep the turbine gates at the proper opening to supply water for any load which may be applied to the turbine, and to keep the speed constant at all loads and within set limits under load variations. A relay valve connection from the fly balls, controlled through dashpots and a spetial regulating mechanism, admits and discharges oil from each side of the piston in the main cylinder as required, thus adjusting the cylinder and the gates as the load changes.

Foundations.—The foundations for such a heavy unit, which weighs nearly 400 tons, are necessarily very massive. The generator, situated nearest the tailrace end of the power house, is carried on a massive arch, 28 ft. span and semi-circular, rising from the bottom of the excavation for the discharge water, 31 feet below the level of the power house floor and running 20 feet back from the wall of the building. The remaining 37 ft. width of the building is taken up with the various pits connected with the turbine inlets, outlets and drains. The excavation runs from 13 to 31 feet below floor level. An arch 10 ft. in diameter allows the penstock to enter the building at the front of the building.

The forms and centres for the arches, draft tubes, relief valve, etc., entailed much special work. Those for the curved draft tubes were built on wooden ribs of 2-in. planking spaced about 2 ft. apart and properly braced with ½-in. x 3-in. poplar strips nailed thereon to give the proper form to the tube. Openings with small clearances were left for parts of the machinery below floor level, which, after being placed and secured in position were grouted in place in the usual manner.

Generator

This machine, directly coupled to the turbine described, was built and installed by the Canadian General Electric Company, of Peterborough and Toronto. It is capable of generating 9,375 kv.a. at 257 r.p.m. and 4,000 volts, with a continuous overload capacity of 25 per cent. or, 50 per cent. for one hour. The total weight of the machine is 298,000 lbs., and the revolving field weighs 153,000 lbs. The armature is wound in two separate circuits entirely independent of each other, each connected to a bank of air blast transformers. The unit is of the horizontal shaft type; the shaft diameter being 13 inches.

The field is supplied with direct current from exciters

(Concluded on page 161)

The Larger Use of Reinforced Concrete in Sewer Construction

By W. W. Horner*

UP to 1900 sewers were constructed of brick and stone, sometimes accompanied by concrete backing and occasionally of plain concrete. From long experience with these materials, certain typical sections had been developed of which the circular and egg-shaped brick sewers in the smaller sizes were more common. For larger sizes some form of arch with a generally flat invert was used. In much of the older work the base or bottom was actually a timber grillage, and contained lumber up to 12 x 30 in. sticks. In the later construction an inverted arch of cut-stone or brick on a concrete bed, was substituted for the timber. Above the base the sewer consisted of heavy sidewalls or abutments and a semi-circular brick or stone arch, haunched with rubble masonry and later with concrete. Occasionally on projects of great magnitude, a closer study of the lines of pressure resulted in modifications of this type and some examples of elliptical, catenary and parabolic arches were found. It appears evident that most of the sewer arches in that period were not the result of stress analysis but were proportioned by arbitrary rules resulting from a study of existing structures.

About 1900 reinforced concrete had been taken up in many fields of construction and had been applied to long-span arches and the advantages of its use in sewer construction were soon appreciated. During the next five years, many examples of concrete sewers are found, although with a few exceptions the reinforcement consisted of wire mesh or expanded metal and there was an evident tendency on the part of the majority of engineers to use rather heavy sections similar to the plain masonry types. A few examples are also found of extremely radical designs involving very light sections heavily reinforced. These two extremes suggest the difference between the sewer engineer adapting his designs to reinforced work and the concrete expert breaking into the sewer field. In the last 10 years, all of these ideas have been through the melting pot, and we are beginning to find certain standard types of reinforced concrete sewers used generally. These are the horseshoe type varying in proportions from the semi-circular to those of about equal height and width, and the elliptical usually constructed as a five-centered arch. Of exceptional advantage under certain conditions the box or slab section is often employed, but under average conditions it is less economical than the other types. The circular sewer is difficult to construct in what is known as "monolithic" work, that is, if built in place, but the circular reinforced concrete pipe developed along other lines has become standard construction in size up to about 8 ft. It is unit work and may be considered as a factory product, and for that reason a much more satisfactory concrete can be secured through its use than is generally obtained in monolithic work.

Cross-Sections.

In many cases, the shape of the sewer will be controlled by local conditions. In wet ground the invert must be kept as high as possible and a broad shallow section results. For such cases the semi-circular shape is the most economical, and in fact is about the limit of distortion in that direction, as computations show that little further decrease in height can be obtained by adopting a wider, flat segmental arch. For such extremes where the semi-circular is not satisfactory, it is possible to design a box section, and if necessary, a multiple box, though this latter should always be compared with a similar multiplication of normal arches before being adopted.

Where the sewer is deep, and in particular, if in rock, there is usually economy in making the heights of the section greater than the widths, and if in deep rock cut, it is possible to use plain concrete sides and a flat arch abutting on the rock.

Under average conditions the most economical section is undoubtedly one approaching nearly to the circle, that is, having width and height about equal, but on account of the difficulty of securing satisfactory construction with a semi-circular invert, a segmental invert (usually a 45- to 60-deg. segment) has been common.

Use of Arch Sections

For loads due entirely to earth pressure and for sewers through fully developed territory where the loading can be definitely determined, arch sections of the semi-elliptical or similar types can undoubtedly be used to advantage, as the concrete can be worked in direct compression for the normal load and reinforcing put in to allow for unusual conditions. But where the loads cannot be predicted with reasonable accuracy or where extreme loads of opposite character must be provided for, there will be little difference between the semi-elliptical and semi-circular sections and there is undoubtedly a prejudice in favor of the latter.

The great advantage of the reinforced arch for use in sewer construction lies in the economy in material. Except in extreme instances where the box or slab construction is employed, an equally satisfactory sewer may be built of brick and mass concrete, but in large sizes, 8 ft. or over, the reinforced concrete sewer requires only from 60 to 80 per cent. as much masonry as the "gravity" type. Also where the amount of concrete per foot is sufficient to warrant an efficient plant the unit cost of the concrete should be somewhat less than that of good brick masonry. In addition to the saving in masonry, there is usually an accompanying difference in excavation and in deep work this may be a material consideration. Finally there may reasonably be a difference in required size of sewer due to the greater smoothness of good concrete work, which amounts to between 5 and 10 per cent. reduction in mean diameter.

It has been the writer's experience that for sewers up to about 8 ft. in diameter, brick work is probably more economical than concrete and that for larger sizes the reverse is true, the saving in favor of concrete increasing with the size. This is, of course, in the light of local conditions and might be modified for other cities. The comparison is based on work in the open where sufficient ground is available for plant and

* Engineer in charge of design, sewers and paving, St. Louis, Mo., before American Concrete Congress, Chicago.

material storage, and the statement must be again modified if the work is to be done in congested districts. As an example, it was recently considered economical to build a 14-ft. sewer of brick because of its location through a solidly built up residence district of the city.

There can be no question that reinforced concrete is the natural engineering solution for the problem of large sewers. If reasonably designed and carefully constructed, it gives the best and cheapest sewer. In the hands of a designer not thoroughly familiar with the conditions surrounding sewer construction and maintenance, or of a contractor not experienced in reinforced concrete work, it is likely to be a dangerous material and it is a much too common occurrence that work is handled under just these conditions. The fact that many of these sewers are built by contractors whose experience has been with massive masonry, has not tended to add to the safety of the finished work.

While some of the old sewer engineers have built reinforced sewers that would be reasonably safe and without reinforcement, there are many examples of exceptionally thin sections. These, the writer believes, are the result of assumptions that concrete can be placed in a sewer ditch with the same success as in a building and that the loading can be accurately forecasted. To eradicate this idea a brief description of average construction conditions may be warranted.

Construction

There is no class of work in which so many difficulties surround the successful placing of reinforced concrete as in sewer work. Sewers are usually constructed along public streets or alleys at considerable depth below the ground, or if in shallow excavation, are likely to be along the general trend of some water course and may often cross and re-cross a running stream. For these reasons, the excavation is usually difficult and the sides of the trench hard to support. Probably the best work can be secured in the open country, where the sides of the trench can be sloped. In this case, there is no cross bracing to complicate the form work and outside forms can be used and removed. Where the sides of the trench must be vertical, it is necessary to put in horizontal planking and cross bracing as the excavation proceeds, and it is economy to use as little lumber as possible below the spring line of the sewer, as such lumber is necessarily concreted in and lost. For the same reason, outside forms are not customarily used for the lower portion of the work.

When the excavation is complete, the invert is concreted. In rock or in dry ground, this can be done efficiently but if water or mud is present, a portion of the concrete is sure to be unsatisfactory. With very bad bottoms, it is often necessary to place a raft of extra concrete and allow it to set before attempting to place reinforcement. If such conditions appear possible, good practice will provide for this work in both specifications and estimate and many reasonably provide for underdrains to relieve the new concrete of damage from water flowing from the trench ahead. Unless the specifications are to provide that the work is to be expensively delayed, it should be noted that there will be quite an amount of working over and across the new invert while the concrete is setting and exposed bars left for splicing are likely to be bent and jarred and their bond value in the invert concrete decreased. Also because of these stub bars, it is usually impracticable to protect that portion of the invert from dirt and rubbish. While it is generally the custom to leave the sides of the invert rough to furnish a bond with the arch, it is an open question whether the finishing of this concrete smooth is not the lesser evil, as it can then be thoroughly and efficiently cleaned before additional concrete is laid.

Before the arch forms are set, it is necessary to remove cross bracing up to the crown level, and it must be replaced with verticals bedded in the new invert and cross-braced above the crown. Even with the most careful work, this will produce some disturbance with the sides of the trench and may even allow a bulging of the side plank enough to protrude within the neat measurements of the sewer. To widen and rebrace the section from the surface down may be expensive and hazardous as well as disorganizing, and the engineer often faces the problem of modifying the section instead. The writer recalls instances where the contractors have even asked permission to fill the whole trench to the top of the sewer with concrete at their own expense, rather than to attempt the re-excavation, and the construction engineer must be able to decide whether the deficiency in thickness at the sides can be compensated in this matter.

Collapsible steel forms are usually favored for the arch, and if kept well cleaned and oiled produce the best interior surface, but well-made wooden centers carefully planned will result in more satisfactory work. The choice will usually depend on the contractor's organization and schedule, as greater progress with one outfit can be secured if the collapsible forms are used.

Under the conditions prevalent in this work, the setting and holding of the arch reinforcement in accurate position is especially difficult and the importance of accuracy is rarely appreciated by foreman and laborer. When properly set, the rods are difficult to hold during concreting, as it is often necessary for the men to stand on the reinforcing while spading the concrete. The cost of special chairs or holders for the reinforcement is usually well warranted.

Breaks Up the Aggregate

The placing of the concrete is made especially difficult because of the double mat of reinforcing bars, which tend to break up the stream of concrete and to cause a separating out of the aggregate. The concrete is also likely to be lowered in quality by an almost unavoidable leakage of water. The concrete is also contaminated to some extent by earth and rubbish knocked from the surface into the forms. There occurs, also, even in the best regulated work, certain small slips of earth from between the side planking, and it is possible that portions of the clay or loam may be churned into the concrete before it can be cleaned out from between the tangle of reinforcement

In view of the unavoidable construction contingencies inherent in this class of work, the writer would recommend to the designer the following prescription:

1.—Use the best grade of concrete and considerable excess of mortar.

2.—Do not work concrete at more than 450 lbs., unless the construction conditions are to be exceptionally favorable.

3.—The concrete cover outside of the steel should be at least 2 ins.

4.—Use a minimum thickness of concrete of about 9 ins. unless the work is close to the surface, or is to be built under very favorable conditions, and increase this minimum and also the cover over the steel if the conditions are likely to be very unfavorable.

5.—Specify the setting of the reinforcement with especially designed holders. These might be made of cast iron and left in the concrete.

6.—If there is any possibility that the trench will be very wet or mucky, provide for a sub-case of concrete and provide means of keeping the trench work away from the work, if possible.

7.—To secure a concrete that will flow into place with the least assistance, a specification for a 2½ or a 3-minute mix should be seriously considered, as might also the use of hydrated lime. This would naturally result also in a denser and more waterproof concrete and might be a very considerable factor in prolonging the life of the reinforcement.

8.—Provide for a lining of vitrified brick for the invert, or at least provide an excess internal area to allow for such a lining at some later date. This is of more importance in maintenance than in construction, as under average conditions it is easier to obtain a reasonably smooth invert with the brick than to attempt to finish the concrete itself.

9.—Specify cold weather methods. Concrete can be placed satisfactorily and economically at even a zero temperature, if proper precautions are taken. It should be noted, however, that it is quite easy to overheat the finished concrete and to drive out a portion of the water.

In the St. Louis work, it has been customary to heat the water by turning exhaust steam into the water tank whenever the temperature goes below 40 degrees or whenever there is frost in the materials. In colder weather, steam coils are used in the said storage piles and often in the piles of coarse aggregate. It is also customary in freezing weather to place salamanders inside the arches and to hang tarpaulins at each end of the unit constructed. The top of the sewer has generally been protected by a covering of tarpaulin or plank, on top of which manure is piled

Loading

The loads to be considered are first, direct weight of the earth filling; second, horizontal or inclined pressures induced by the weight of this filling and the adjoining earth; third, pressures due to transmitted surface loads.

The relative values of these pressures will depend on the depth and size of the sewer and on the use to which the ground surface may be put.

Vertical Loads—It is always safe and usually reasonable to design for vertical loads equal to the full weight of the superimposed earth. Recent investigations of small sewers and pipes have shown that, due to some arching action of the earth itself, the full dead weight is not always applied to the sewer. The allowable reduction, however, seems to be of little importance until the depth of the fill is at least equal to the width of the trench and would only amount to about 25 per cent. when this depth is twice the width. The work of Marston and Anderson indicates that for depths of 10 to 15 times the width only 30 to 40 per cent. of the load is carried by the sewer. For a sewer more than 8 ft. in width, the depth of cover will rarely exceed twice the trench width, so that the reductions are hardly worth taking into account. There must also be reasonable doubt whether the gradual settlement does not finally increase the weight on the sewers considerably above the values given.

Horizontal Pressure.—There is so much doubt as to correct values of horizontal pressures, even for a given soil condition, and the pressures will vary so greatly in the different soils that the designer can only attempt to make a safe guess at the correct amounts to be used.

According to Rankin's theory, the intensity of horizontal pressure cannot be less than one-third of the intensity of vertical pressure for a particular depth and in ordinary clay it is customary to consider it as one-half of the vertical. For saturated ground, the earth will approach the condition of a fluid and the horizontal and vertical pressures would be equal.

Surface Loads.—Where sewers are constructed in city streets, the heaviest surface load would be the weight of a road roller, and this might be taken as 15 tons on an area of 5 sq. ft. at the surface, distributed downward along an angle of 30 deg. with a vertical. At a depth of 10 ft. this would approximately be equal to 200 lbs. per square foot on an area of 11 x 15 ft., or roughly equivalent to an additional 2 ft. of fill. If there are railroads crossing the line of the sewer, or if it seems at all possible that such roads be built, the sewer should be designed for locomotive loading in the same way. A fair value for this loading would be 80 tons on an area of 10 x 20 ft. at the surface. Distributed as above, this would be equivalent to about 300 lbs., per square foot over an area of 20 x 30 ft., at a 10-ft. depth and would give the same pressure as 3 ft. of additional fill.

For very light covers, these values would, of course, be increased, and it might even be reasonable to provide for impact, but for depths of cover for 6 ft., or more, it is usually satisfactory to treat such loads as additional weight of earth and allow them to increase both the vertical and the horizontal pressures. Allowance for foundations and for piles of material may be handled in the same manner.

Combination of Loading.—For final conditions, that is, after the backfill has reached a state of settled equilibrium, the sewer will be subject to a direct combination of horizontal and vertical pressures. It should be noted that the greatest bending moments in the arch will be due to vertical loads alone. Horizontal pressures usually induce moments of the opposite kind. The combination of vertical and horizontal pressures, therefore, while increasing the direct normal compression in the arch, will give smaller bending moments than those from the vertical loads. While the stress in the arch may finally reach the values derived from a proper combination of the two classes of forces, yet it is quite common for the sewer to be subject only to pressure of one kind during the construction period. Examples of this are as follows:

(a) A trench is excavated through hard clay which requires little bracing and will stand vertically for some time. The trench is backfilled with the same material. Then the full weight of the backfill may act vertically on the arch for some time before the sides of the trench finally slip and add also a horizontal pressure.

(b) In the example above, the sides of the trench may slip in against the sewer before the backfill is placed, producing heavy horizontal pressure and bending moments of reverse character.

(c) A trench through soft ground is held by sheet piling. When this piling is pulled there may be an appreciable time before the earth at the sides closes in and fills the void left by the piling. During this time the vertical loads only will act.

(d) In the above example, if the sheet piling is drawn before the backfilling is started, the earth at the sides may cave in and produce horizontal pressure with very little vertical load.

Loads of these kinds will only occur while the arch is new, possibly before the concrete has attained more than half of its normal strength. If the design contains a factor of safety of four for combination of pressures, and the concrete is only 10 or 15 days old, the arch would be about on the point of failure for vertical loads.

It would seem, therefore, that the design should provide for vertical loads alone, or at least in combination with a very small horizontal pressure on the arch only (not against vertical side walls.) This loading will be critical and from it the dimensions of the concrete and one set of reinforcements will be determined. The arch so determined should then be designed for horizontal pressure in combination with as little vertical loads as may seem possible. From this the reverse reinforcement may be calculated. Finally it is of interest to compute the stresses under normal combination of the two.

Three Fine New Schools for Municipality of Kildonan, Man.

Three large schools have recently been erected by the Sutherland Construction Company for the Municipality of East Kildonan, a suburb of Winnipeg. Each of these schools is of the same design and practically the same size. We illustrate one herewith—the Lord Kitchener School.

These three schools are thoroughly modern and are of absolutely fireproof construction. They each have a stone and concrete foundation. The outside finish is Fort William pressed brick, backed with hollow load bearing tile, the division walls being of the same tile, which material was supplied by the Dominion Fireproofing Company, Winnipeg. These tiles are made in Medicine Hat, Alta. All windows throughout these buildings are steel sash.

Each school is two stories and basement high and cost approximately $50,000. The basements, which are 11 feet high, are used as playgrounds. The total height of the schools is 52 feet. The interior finish is oak, and the floors in the corridors are of mastic asphalt. All floors in classrooms are reinforced concrete covered with maple flooring. The roofs of all three schools are sheet metal. The buildings are steam heated and electric lighted.

The electric light contracts on the three schools were let to Scorer Bros., Winnipeg. The plumbing and heating on two schools were let to Gates & Sons, while on the third school this contract was let to J. Thompson. The painting contracts were let to Robert Crawford, while Brown & Rutherford supplied all the interior finish. The Alsip Brick and Tile Company supplied all the common brick used in these schools. The Winnipeg Steel Granary and Culvert Company supplied the sheet metal and calimini doors in corridors. The stone used was supplied by Gillies & Son. The mastic asphalt in the corridors was put in by the Canadian Johns-Manville Company, and the ornamental iron work and stairs were supplied by the Vulcan Iron Works, Winnipeg. All these firms except the one supplying the pressed brick belong to Winnipeg. J. D. Atcheson & Co. were the architects for the three schools.

Mr. John E. Russell, 307 Logan Avenue, has been appointed Toronto representative of the Union Cement Company, Limited, of Owen Sound, Ont.

Lord Kitchener School, East Kildonan, Man.

A Gyratory Foundry Riddle

The cost of labor is the largest item in the making of castings, and the device described herewith materially reduces this cost. This device is a new and unique foundry riddle of the gyratory type. The motion of the riddle is obtained by the inertia effect of an unbalanced flywheel which causes every part to gyrate. This motion is unusually well adapted for sifting sand, since a lot of the energy is not wasted in throwing it against the ends of the compartment, as is done in a reciprocating type. Each particle of sand travels around in a circle, so that the small particles reach the sieve in the shortest possible time and the sifting takes place with great rapidity. The outfit complete weighs only about 90 pounds and so can be easily moved from place to place as it is needed. The riddle is particularly useful suspended from a trolley running on a cable stretched parallel with the line of moulders in the foundry. Owing to its design there are no obstructions in the way of a shovel, and, being

supported from above, a wheelbarrow can be run under the riddle for receiving the sand.

The riddle is operated by a Westinghouse totally enclosed 1/6 h.p., vertical motor, made especially for the Great Western Manufacturing Company, of Leavenworth, Kansas, who manufacture the outfit. As the total power is obtained from the unbalanced effect of the flywheel the horse-power to drive the riddle is very low and a cord and plug fitting any lamp socket is furnished with the motor so that no special wiring is necessary for the installation of this machine. The motor has a ball thrust bearing, and a total of only three bearings are used in the drive, all of which are dust proof. The sieve is 20 inches in diameter, and with this size the riddle will do the work of ten men sifting sand by hand. In fact, the sifting is done so quickly that it will riddle faster than one man can shovel in the sand. As the sieve does not have to be connected to the motor by connecting rods, etc., it can be easily and quickly removed from the clamping device for dumping. The machine mixes as well as sifts, so that one turning of the sand is eliminated, and not only the time of making the mold is reduced, but a better mold is insured after drawing the pattern.

Conference on Road Construction

(Continued from page 152)

ing the superintendents in their work. Mr. Hogarth replied on behalf of the engineers, expressing their appreciation of the way the superintendents entered into the discussion of their various papers, and the interest shown. Their aim had been to make the conference as practical and useful as possible, and from the interest displayed it was evident they had to some extent succeeded.

Mr. Huber, member of the Department's staff, spoke on the tremendous importance of having the records accurately and clearly made out, and asked the engineers to co-operate with them in this respect.

Mr. McLean Is Appreciated

On Friday morning, Major Sheppard, Mr. Talbot, Mr. Wilson, and Mr. McClure, on behalf of the road superintendents, presented Mr. McLean with a gold-headed cane, suitably carved, to commemorate the event and in appreciation of his services to the county road superintendents in assisting them in their work; also as extending to him their hearty congratulations on the appreciation of his merits by the Government indicated in his appointment as Deputy Minister to the new Highways Branch of the Department of Works.

Toronto Section C. S. C. E.

(Continued from page 142)

dam, which is the best and largest example of hydraulic fill construction in Canada, is 99 feet in height, 950 feet in length exclusive of spillway. The storage obtained by building this dam amounts to 180,500 acre feet, or 7,873 million cubic feet. The lecturer decribed in detail the hydraulic sluicing operations in which 4 inch and 5 inch monitors were employed with a nozzle pressure of 80 lbs. per square inch. Of the 550,000 cubic yards of material in the dam, 427,000 cubic yards was placed in position by sluicing, the remainder—consisting of heavy rock toes—being placed by electrically operated cableways. A description was also given of the intake works for the supply of water to New Westminster, and some interesting data regarding the rainfall in this part of British Columbia which has varied at Coquitlam between the extremes of 132 inches and 190 inches, the average being 153 inches per annum.

At the conclusion of the paper an interesting discussion took place and many questions were asked the lecturer, after which a hearty vote of thanks was tendered Mr. Conway for his very interesting and instructive address.

Invitations have been sent to the governors of the several states of the Union and to the lieutenant-governors of the provinces of Canada, with the request that they attend and appoint delegates to the Thirteenth Annual Convention of the American Road Builders' Association, to be held in Pittsburgh, Pa., during the week beginning February 28th.

Branch Managers' Convention Great Success

The last week in January was a notable one for the Trussed Concrete Steel Company, as it marked the first annual convention of the branch managers held at their main plant at Youngstown, Ohio. Men gathered from every section of the country to co-operate in formulating improved methods which would render greatest service to their clients. Not only every section of the country was represented, but representatives were present from far distant countries, including Japan, Hawaii, South America and Porto Rico. Fully one hundred men were in attendance.

Calgary Branch C. S. C. E.

The Calgary Branch of the Canadian Society of Civil Engineers held its first dinner of the season at the Alexandra Hotel on January 13th. A. G. Graves, Commissioner, City of Calgary, gave a very interesting address on the "Administration of Public Utilities" and showed that Calgary's public utilities compared favorably in service and cost to the public with other cities in the Dominion and elsewhere. His Worship Mayor Costello and Commissioner J. H. Garden were also guests of the Branch. Mr. S. G. Porter is secretary-treasurer of the Calgary branch.

National Iron Works get Contracts

The National Iron Works, Limited, of Toronto, have been awarded a very considerable contract by the city of Ottawa. This contract consists in the supply of 18-in., 20-in., 24-in., 30-in. and 36-in. cast iron water-pipe, aggregating some four thousand tons. This contract is in connection with the city of Ottawa's new water system, and delivery will have to be made during the spring and summer of 1916. Mr. R. L. Haycock is waterworks engineer of the city of Ottawa, and has charge of the designing and construction of the new system.

Mr. Mack Lectures on "Condulets"

At a meeting of the Toronto Branch of the Ontario Electrical Contractors' Association, held in the association rooms on Wednesday evening, February 2, Mr. Ed. Mack, of the Crouse-Hinds Company of Canada delivered an address on his company's products. Mr. Mack illustrated his remarks from the very complete catalogues published by his company and also from an extensive line of samples of the Crouse-Hinds condulets. He described in detail the process of manufacture, pointing out the care taken at every stage in order to insure perfect workmanship so as to avoid difficulties when the material reaches the job. He also fully explained the original system of catalogue numbers adopted by his company, whereby a numeral is selected for each size from ½ in. to 6 in., pointing out where this system worked to good advantage when ordering condulets with a multiple of outlets, such as T or X. Mr. Mack also pointed out that in view of the fact that they carried at all times three separate and distinct stocks—two at different stages of manufacture and one of the completed article—they were in a position to fill any order from either of these stocks, stating that if the fittings required were not found in their completed stock it would only take a few hours to finish from the rough state and make delivery. Mr. Mack also explained that the keynote of his company's policy was "Service to the Trade," and they stood at all times ready to make delivery of any special fittings or special drilling of fittings or covers to meet any particular requirement.

Mr. Mack's address occupied about an hour and a half and was followed by the members with keen interest. Arrangements were made for a party to visit the Crouse-Hinds factory, at some date in the future, where, as Mr. Mack stated, they would be shown every step in the manufacturing process.

The Kaministiquia Power Co.

(Continued from page 155)

which were already installed, at 110 volts, and is regulated, for constant voltage at terminus of transmission lines, by means of a Tirrill regulator in the exciter circuit. The transformers are of the air blast type and consist of three single phase units installed over an air chamber, each of 1,475 kw. capacity. Interconnected between generator and transformers are selector switches, with connections to a common 4,000 volt busbar, which enables the generator to supply current to other banks of transformers in case of trouble.

Switchboard

The usual recording, indicating, and switching apparatus is installed in the generator circuits, being connected to the switchboard through current and potential transformers to eliminate high voltage on the switchboard. An ammeter is installed in one phase of each bank of three high tension transformers, to indicate the proper equalized loads upon each. The switching apparatus is installed in reinforced concrete compartment, with switches in front and current transformers and wiring at the back; the latter, for all high tension work at 25,000 volts, is bare No. 4-O copper on porcelain insulators. Over-load, time limit relays guard the transformers and generator against excessive short circuits. A motor controlled generator rheostat adjusts the field, with a control switch on the generator panel.

In view of the fluctuating voltage of the exciter circuit, due to operation of the Tirrill regulator, a small 80 amp. hour battery has been installed to connect to the control circuit of the switchboard and provide a few lights in the power house in case of short circuits or other trouble cutting the generator and exciter supply down. This is charged from a small motor generator set with a panel near the main switchboard, so that the usual attendant may operate it. The same set also serves to charge the battery situated at the forebay, through a special overhead line. Push buttons and indicating devices on one panel of the switchboard indicate the position of the butterfly gates at the forebay and control the closing of each gate. The power house lighting, which previously had been from unshaded carbon lamps in lines along the walls, was changed to ceiling tungsten lights with concentrating reflectors, with six 150 watt tungsten units in a space 28 ft. x 50 ft.; this gives a more even distribution of light and, although at a height from the floor of 32 ft., gives sufficient light for all ordinary work.

Staff

The entire work was carried out under the direction of Messrs. R. S. Kelsch, of Montreal, Consulting Engineer to the company, and W. L. Bird, manager. Mr. Geo. Lewis was construction superintendent for all concrete work. The writer was responsible for all preliminary engineering data on aqueduct, penstock, generator foundations, etc., and for designs for aqueduct forms, forebay battery house, valve house and workshop and details of all small work, with inspection of electrical equipment and hydraulic work.

Montreal Tramways Company, Montreal, have awarded a contract for the first unit of their announced addition to their steam-generating plant. This will be a steam-driven turbo generator of a capacity of 15,630 kv.a., considerably the largest ever installed in Canada. It will be 60-cycle, three-phase, 1800-r.p.m., and generate at 5600 volts. This unit is being supplied by the Canadian General Electric

60,000 Kw. Units Contemplated

President E. M. Herr of the Westinghouse Electric & Mfg. Company, in a recent address before the Railway Club of Pittsburgh, said, "Due largely to the wonderful development in the steam turbine and its direct-connected electric generator, and the remarkably flexible, efficient and easy distribution of electricity, we are on the eve of notable advances in the utilization of electric power.

"First—the modern steam turbo-generator makes it possible to concentrate enormous amounts of power generation in one place.

"Second—this makes possible and advantageous very large individual generating units. The growth in the capacity of generators has really been enormous, made possible by the steam turbine.

"Third—Electricity can be transmitted long distances in large or small quantities and its characteristics changed at will all with small losses and at comparatively low cost."

The speaker then proceeded to trace the development of large generating units as exemplified by certain notable installations of central stations, industrial, and railway plants, and then discussed the effect of the concentration of such a large amount of power in one station. Mr. Herr said the building of units as large as 50,000 and 60,000 kw., was contemplated.

New Electric Railway in Three Rivers

With a fair amount of ceremony, the Three Rivers Traction Company, a subsidiary of the Shawinigan Water and Power Company, on December 11 inaugurated their electric tramway service. The line, of single track, is about three miles long, and runs in the form of a circle around the city, starting at the Canadian Pacific Railway station, taking in the residential district, along the river front, and returning to the station via the chief business thoroughfare. It has been decided to extend the system by building a line to Cap Madeleine, (a popular pilgrimage centre), which will also connect the Wayagamack pulp and paper plant and other industries with Three Rivers. Power is supplied by the North Shore Power Company, two Canadian Westinghouse 250 k.v.a. 550v. d. c. motor-generator sets having been installed for the purpose of the line. The poles are of steel in the residential and business sections and of wood in other districts. A car barn to hold ten cars, with repair shop, has been constructed. The six cars, manufactured by the Ottawa Car Manufacturing Company, are of the pay-as-you-enter type, each car being in charge of one man only who acts as motorman and also regulates the entrance and exit of the passengers. At the inauguration, speeches were made by the Hon. J. A. Tessier, the Mayor of the city and Minister of Roads for Quebec; Mr. Julian C. Smith, the vice-president of the company; Mr. W. S. Soper, of the Ottawa Car Manufacturing Company; Hon. Jacques Bureau, and others.

Trade Publications

Pumps—bulletin 108A, by the Wheeler Condenser and Engineering Company, Carteret, N. J., describing centrifugal pumps, single stage, double suction, up to 300-ft. head.

103. **Steel tubes.**—A Birmingham firm is open to purchase close-joint steel tubes for bedsteads or electric conduit work. Prices should include delivery Bristol or Liverpool, the former preferred. Samples may be inspected at the Department of Trade and Commerce, Ottawa.

Brownhoist—catalogue D, 1916, by the Brown Hoisting Machinery Company, Cleveland, Ohio, describing, with complete illustrations, tramrail systems, trolleys and electric hoists for handling all kinds of material, as manufactured by this company.

Dams and Weirs—by W. G. Bligh, Inspecting Engineer of Irrigation Works, Department of Interior, Canada. American Technical Society, Chicago, publishers. An analytical, practical treatise on gravity dams and weirs, arch and buttress dams, submerged weirs and barrages. The scope of this work may be judged from the following chapter headings: Gravity dams; Design of dams; Unusually high dams; Notable existing dams; Special foundations; Gravity overfall dams or weirs; Arched dams; Multiple arch or hollow arch buttress dams; Hollow slab buttress dams; Submerged weirs founded on sand; Open dams or barrages. Size, approximately 5½ by 8½ inches; 206 pages; well illustrated.

Personal

Mr. Paul F. Sise, vice-president and general manager of the Northern Electric Company, has been appointed adjutant of the 148th, a battalion organized in Montreal by Lieut.-Col. Magee for overseas service. Mr. Sise was formerly captain in the Victoria Rifles, and when the war broke out joined the Canadian Officers' Training Corps, which is affiliated with McGill University. Later, when the McGill Auxiliary Battalion was formed, Capt. Sise was in command of "D" Company, and afterwards of "A" Company, McGill Contingent, Canadian Officers' Training Corps. Considering the important executive position held by Capt. Sise, to say nothing of the responsibilities which such a position entails, it is impossible to underestimate the effect such a splendid example will have on his fellow Canadians. It typifies the calibre of the man and the loyal motives which are inducing our best citizens to answer the call of their country, and gives us certain confidence in the ultimate outcome of this great struggle.

Capt. P. F. Sise

Capt. Sise is only 36 years old. He was educated at Bishop's College School, Lennoxville, and at McGill University, from which he graduated with B.Sc. degree. He was one of the organizers of the University Club, Montreal, and is also a member of St. James Club and a Governor of the Western Hospital.

Mr. S. V. Kendall, Managing Director of Wm. Cowlin & Sons, Limited, general contractors, Toronto, has recently returned from England.

Mr. C. H. Rust, city engineer of Victoria, B. C., read a very interesting paper on the Sooke Lake Water-works at the annual meeting of the Seattle branch of the American Society of Civil Engineers held on January 31.

Mr. S. C. Wilcox, a former civil engineer with the C. P. R. at Kenora, Ont., and also at Winnipeg, has received a commission as Lieutenant in the 100th Battalion now in training at Winnipeg.

Obituary

Urgel Pauze, president of the Pauze & Fils Company, Limited, contractors, Montreal, is dead.

The death occurred on February 4th of Mr. Donald A. Munro, of Wolfville, N. S., at the age of 86. Mr. Munro was a prominent business man in the town. He carried on the business of carriage making for some years, finally taking up contracting and building and mill work.

A pioneer railroad builder of the West died recently in the person of Mr. N. P. Anderson. Mr. Anderson, who was a native of Sweden, came to Canada thirty-five years ago, and for twenty-nine years held responsible positions with the C. P. R. He was engaged on the construction of the C. P. R. through the mountains, and lived for many years at Revelstoke, B. C.

Mainly Constructional

East and West—From Coast to Coast

The Jos. Denis Company, contractors, Montreal, Que., have registered.

The Advance Engineering Company, Limited, Toronto, have secured a charter.

A charter has been granted to the Canadian Rock Drill Company, Limited, Toronto.

The Delorimier Architectural Steel and Iron Works, Montreal, Que., have registered.

Hamilton is erecting a nurses' home in connection with the Mountain Hospital at a cost of $30,000.

Forty-five building permits, of a value of $60,590, were taken out in Medicine Hat, Alta., during 1915.

Engineering and Construction Company, Limited (Laurin & Leitch), Montreal, Que., have registered.

A contract for a fuse factory has been let to the Atlas Construction Company, Montreal. The steel will be supplied by the Dominion Bridge Company.

Mr. G. B. Mitchell, C. E. and general contractor, has removed from the Jacobs Building, St. Catherine Street West, to 509-10 New Birks Building, Montreal.

The value of the building permits issued by the city of St. Catharines in January, 1916, is about three and a half times the value of those issued in January, 1915.

According to a reported newspaper interview with Mr. Grant Hall, of the Canadian Pacific Railway Company, the Rogers Pass Tunnel will not be electrically operated at present.

During the month of January, 1916, the city of Montreal issued 44 building permits, of a value of $174,160. In the same month of last year 73 permits, of a value of $203,261, were issued.

A company known as the Pembroke Iron Works, Limited, has been formed, with head office at Pembroke, Ont., and a capital of $100,000. The provisional directors are J. F. Munro, P. White, and T. Pink.

At the request of the Dominion Government, the International Nickel Company have undertaken to establish a plant for the refining of nickel in Canada. It is hoped that this plant will supply the entire needs of Great Britain and Canada.

Provincial Stone and Supply Company, Limited, have opened an office at Room 200, McKinnon Building, Toronto, for the purpose of dealing in crushed stone and builders' supplies. Mr. Robin Boyle, formerly of Niagara Falls, is manager.

Plans for a bridge over the Valley Inn, Hamilton, to be used in connection with the entrance of the Toronto-Hamilton highway to the city, will be considered shortly by the Board of Control. It is estimated that the bridge will cost $250,000.

In connection with the plans for reconstructing the Ottawa Parliament Buildings, two architects, Mr. John A. Pearson, of Toronto, and Mr. Marchand, of Montreal, have been appointed to examine the old walls and see how far they can be utilized in rebuilding.

La Fonderie d'Acier de Quebec, Limited, is the name of a new Quebec concern incorporated by E. Massicotte, of Sainte Anne de la Perade, and J. A. Larue, E. Trudel, W. Boulet, H. Groleau, E. Picher and N. Caouette, of Quebec. The capital stock of the company is $149,000.

According to a reply in the House of Commons by Hon. Frank Cochrane to a question by Mr. J. H. Sinclair, nearly $15,000,000 has already been spent on the Hudson Bay Railway project, and it will take at least another $10,000,000 to complete the undertaking. On the railway itself $9,557,340 has been spent in dredging, lighting, and other improvements at Port Nelson.

The following officers have been elected by the Engineers' Club of Toronto: president, W. A. Bucke; first vice-president, E. L. Cousins; second vice-president, L. V. Rorke; third vice-president, C. W. Power; directors, H. G. Acres, J. R. W. Ambrose, Alfred Burton, J. B. Carswell, A. G. Cumming, D. A. Dunlap, Arthur Hewitt, Chas. H. Heys, T. H. Stevens, M. P. White, T. S. Young; secretary-treasurer, R. B. Wolsey.

Mr. Burke, of Burke, Horwood & White, architects, Toronto, has been in Orillia conferring with the Town Council as to plans for the municipal building. He was asked to prepare an estimate for the restoration of the old building, with the addition of a foyer, to do away with the winding stairs. By various modifications it is hoped to reduce the cost of the building by $15,000 or more, compared with the plans submitted last year.

The old summer residence of Mr. Charles M. Schwab at Loretto, Pennsylvania, has been moved a distance of more than 1,300 feet on a forty-foot high trestle, and despite the fact that the building was moved over the tops of trees, several gullies and hills, not a picture nor piece of bric-a-brac in the house was shaken out of its accustomed place. The removal, to make way for a modern stone mansion to cost $750,000, is considered one of the greatest feats of house moving ever undertaken in this country.

The Geo. A. Fuller Company, Limited, Montreal, have obtained a contract for the construction of three mills for the St. Maurice Paper Company, Limited, at Cap Madeleine, P. Q. The company is a subsidiary of the Union Bag and Paper Company, Hudson Falls, N. Y., and is an amalgamation of the Cres Falls Company, Three Rivers; St. Gabriel Lumber Company, Limited, St. Gabriel de Brandon; and the Charlemagne and Lac Oureau Lumber Company. The new plant comprises a news print mill, a sulphite pulp mill and a kraft mill. The steel will be supplied by the Structural Steel Company, Limited, Montreal.

The Canadian Steel Foundries, Ltd., intend to expend $100,000 on new equipment, including one or two 35-ton open hearth furnaces.

CONTRACTS AWARDED

Bruce Township, Ont.
The contract for supply of tile and cement has been let by the Township Council to C. S. Woods, c/o the Clerk, J. G. MacKay, Underwood.

Winnipeg, Man.
The Winnipeg Aqueduct Construction Company have awarded a contract to the London Concrete Machinery Company for the supply of six centrifugal pumps, gasoline operated, and two Batch Mixers

Tenders and For Sale Department

Tenders for STREET CARS

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon on **Tuesday, March 14th, 1916**, for the supply and delivery of:

	Tender Numbers
One single-truck double-end street car, completely equipped, ready for operation, for Bloor Street Division, Toronto Civic Railway	37
One car body, double-end, single-truck, for Bloor Street Division, Toronto Civic Ry.	37-A
Equipment for one single-truck for Bloor Street Division, Toronto Civic Railway, electrical equipment	37-B
Equipment for one single-truck car for Bloor Street Division, Toronto Civic Railway, single-truck	37-C

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of city by-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman, Board of Control.

7-7

CITY OF MONTREAL

Refined Asphalt

Tenders, under sealed envelope, addressed to the Board of Commissioners and deposited in their office, at the City Hall, will be received until noon, **Thursday, Fabruary 24th, 1916**, for the supply and delivery of refined asphalt.

The quantity anticipated is about six thousand (6,000) net tons. It is distinctly understood that this quantity is but approximate, and the Board of Commissioners reserves the right to increase or decrease said quantity in any amount at its discretion without entitling the Contractor to any claim whatsoever.

Copies of specifications and forms of tenders may be obtained by the interested parties at the office of the Superintendent of Purchases and Sales, and all necessary information will be given at the Chief Engineer's Office.

All tenders not made on the form furnished for that purpose by the City of Montreal, and not sent in the printed envelope also furnished for that purpose shall not be entertained.

No tenders shall be considered unless the same be accompanied by a cheque accepted by an incorporated Canadian Bank payable to the City of Montreal, for a sum representing 10 per cent. of the total amount of the tender, which tender and cheque shall be enclosed in said envelope.

The lowest or any tender will not necessarily be accepted.

The tenders will be opened in the presence of the interested parties by the Board of Commissioners deliberating in its Meeting Room, at the City Hall, at the first regular meeting of the said Board, following the reception of the said tenders or on the date above mentioned, if the Board is sitting.

By order of the Board of Commissioners.

L. N. SENECAL, Secretary.

Board of Commissioners' Office,
City Hall,
Montreal, February 1st, 1916. 6-7

To Contractors

Sealed bids will be received up to noon, **Wednesday, February 23rd, 1916**, for all trades required in the erection of a warehouse building in Church Street, Toronto. The lowest or any bid not necessarily accepted. Plans and specifications may be seen at the office of the Architect, F. S. Baker, Traders Bank Building, Toronto. 7-7

Board of Education

Sealed tenders, addressed to the Secretary-Treasurer of the Board, will be received until

Thursday, February 24th, 1916
for

Electrical Work at Alexander Muir and Bolton Ave. Schools

Drain Work at Kent School

Ash Hoist and Fire Doors at Withrow Avenue School

Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto. Each tender must be accompanied with an accepted bank cheque for five per cent. of the amount of tender or its equivalent in cash, applying to said tender only. Sureties for all tenders exceeding four thousand dollars must be furnished by Surety Companies. Tenders must be in the hands of the Secretary-Treasurer at his office in the City Hall, **not later than 4 o'clock** on the day named, after which no tender will be received. The lowest or any tender will not necessarily be accepted.

W. C. WILKINSON, Secretary-Treasurer.
7-7 MILES VOKES, Chairman of Committee.

TOWN OF COLLINGWOOD
PROVINCE OF ONTARIO

Waterworks Extensions

Sealed tenders will be received by the Chairman of the Collingwood Water & Light Commission until 8 p.m. on

Wednesday, March 1st, 1916

for the following works:—

(1) Steel Water Tower.

(2) Foundation for Steel Water Tower.

(3) Pumping Machinery, comprising one motor-driven unit of 800 Imperial gallons capacity.

(4) Pump Well and connections.

Plans and specifications may be seen at the office of the Engineers, 204 Mail Building, Toronto, or at the Water and Light Office, Collingwood.

The lowest or any tender not necessarily accepted.

HUGH A. CURRIE, Esq., Chairman.
W. B. H. PATTON, Esq., Mayor.
STEPHEN BURNSIDE, Esq., Commissioner
E. J. STAPLETON, Esq., Superintendent.
CHIPMAN & POWER, Engineers. 7-7

WANTED

Six contractors' dump cars and dinkey. Give particulars. Box 313, Contract Record, Toronto, Ont. 6-7

Township of Brantford

Fonger and Barton Bridges

Sealed tenders, clearly endorsed on the outside, will be received up to noon on **Saturday, February 26th, 1916**, addressed to the Township Clerk, County Building, Brantford.

"A"—For reinforced concrete abutments for Fonger Bridge, containing 225 cubic yards of concrete, and 18,000 lbs. square cold twisted steel reinforcement.

"B"—For steel superstructure, Class "A" loading, clear waterway 70 feet, clear roadway 16 feet, with reinforced concrete deck and latticed hand-railings.

"C"—For reinforced concrete abutments for Barton Bridge, containing 165 cubic yards of concrete and 11,500 lbs. square cold twisted steel reinforcement.

"D"—For steel superstructure, Class "A" loading, clear waterway 80 feet, clear roadway 16 feet, with reinforced concrete deck and three line pipe handrailing.

Each tender must be on the prescribed form and accompanied by a marked cheque for 5 per cent. of the amount of the tender, made payable to the Treasurer of the Township of Brantford.

Plans and specifications may be seen at the office of the undersigned, Room 4, Temple Building, Brantford, from whom tender forms may be had.

ALAN MAIR JACKSON,
6-7 Township Engineer.

POSITIONS VACANT

Wanted by large concern developing electric stoves and heaters, experienced man or school of science graduate to act as foreman or engineer. Further particulars, Box 326, Contract Record, Toronto, Ont. 7-7

AGENTS WANTED

Canadian sales agents wanted by large company manufacturing road making and contractors' machinery. Box 297, Contract Record and Engineering Review, Toronto, Ont. 4-7

Quarry Machinery For Sale

1—No. 6 Kennedy Crusher with extra shaft and head; capacity 50 to 80 tons per hour.
1—revolving screen.
1—main drive belt.
1—60-ft. elevator complete.

For particulars address Box 311, Contract Record, Toronto, Ont. 6-7

Fires

Cape Spencer, N .B.

The oil warehouse and fog alarm, belonging to the Dominion Department of Marine & Fisheries, Ottawa, has been totally destroyed by fire. Loss, $6,000.

Roebuck, Ont.

The Roebuck Cheese & Butter Factory has been completely destroyed by fire. Loss, $10.000; insurance, $5,500. Proprietor, F. Lindsay.

Smith's Falls, Ont.

The Elgin Ward School has been entirely destroyed by fire. Loss, $25,000; insurance, $16,000. Secretary to the School Board, C. T. McBride.

Constitution of Portland Cement

THE chemical constitution of Portland cement, which up to the present time has been more or less of a conjecture, may now be said to have been fairly definitely ascertained. This subject is treated in a very comprehensive way in a paper printed elsewhere in this issue on the subject of "The Chemistry of Portland Cement," by G. A. Rankin, in which he gives the results of his researches on the constitution of cement and the various cementing values of the different constituents. In view of the increasing use of concrete in modern construction and the demand for improved quality which has been brought about in the past, chiefly through perfection of mechanical contrivances and methods employed rather than by any new ideas based on a knowledge of the chemical constituents, further progress and development may be confidently looked for.

Portland cement clinker is the result of chemical combination of the oxides lime, alumina, and silica, with a small percentage of magnesia and ferric oxide. The mixture of these substances, which have very similar properties, is exceedingly fine grained, and it is consequently a very difficult matter to make a quantitative analysis of the constituents. This problem was approached by Mr. Rankin through synthetic treatment of the oxides CaO, Al_2O_3, SiO_2. Heat treatments and microscopic examinations were made to the number of some 7,000 readings on mixtures of these three oxides to ascertain the melting temperature and optical properties of compounds of lime, alumina, silica which form when various mixtures of these three oxides are heated. The data thus obtained is plotted in three dimensions, the concentration of each mixture is represented by a point within an equilateral triangle on the horizontal plane and the magnitude of the temperature by the distance above this plane; the surface thus described represents the melting temperatures of all products obtained when any mixture of the three oxides is heated higher and higher.

The constituents of Portland cement clinker made up only of the pure oxides CaO, Al_2O_3, SiO_2 are the compounds $CaO.SiO_2$ and $CaO.Al_2O_3$; microscopic examinations show that 90 per cent. of Portland cement is composed of these constituents.

The value of Portland cement as a cementing material when mixed with water is largely due to one or other of these compounds. The mixture of these pure oxides when properly burned will produce good Portland cement, with the rapidity of the reactions depending on temperature and the amount of flux formed at that temperature. The requisite amount of flux depends on the fineness of the materials; the finer they are ground the more readily will they combine. In commercial cement there is nearly always present small amounts of magnesia and ferric oxide, alkalies, etc., which have but little effect on the major constituents, but in burning play an important part in causing the formation of a flux at a much lower temperature, thereby accelerating the combination of CaO with Al_2O_3 and SiO_2.

Good Portland cement necessitates that the materials be properly ground, and heated sufficiently high, to complete the chemical reaction. Experience shows that cements containing any free lime are unsound and will in time disintegrate, due to the expansion of the free or unbound lime which reacts with water to form calcium hydrate. The value of Portland cement depends upon the fact that when finely powdered and mixed with water it forms a hard mass; the strength and permanence of this mass depend upon the constituents of the cement. Of these constituents, the compound tricalcium silicate, $3CaO.SiO_2$, is the one which hardens and develops the greatest strength within a reasonable time. It may be said, therefore, that the essential process for the manufacture of Portland cement is the formation of this compound, and that any improvements in the process yielding an increased percentage of this compound will increase the cementing value of Portland cement.

Canadian International Roads Congress

A preliminary programme of the Third Canadian and International Roads Congress, to be held in Montreal, March 6-10, is now made public. The subjects of the papers cover a very wide range, all of course dealing with good roads and to be presented by men who are experts in their respective fields. There will be papers on the construction of roads, methods, maintenance, bridges, machinery, materials, how to successfully meet difficulties of various kinds, etc. Many of the speakers will be practical men, who have had to solve problems either of construction or maintenance.

The Lieut.-Governor of Quebec has promised to open the Congress, and invitations have been forwarded to many prominent men associated with the good roads movement. The following are some of the speakers and their subjects: Messrs. Gabriel Henry, chief engineer, Province of Quebec, "Gravel and Stone Roads"; E. Farfard, chief of equipment department, Province of Quebec, "Handling and Care of Machinery"; Alex. Fraser, engineer, roads department, Province of Quebec, "Highway Culverts"; J. W. Levesque, M.L.A., "Road Laws"; A. F. Macallum, city engineer, Hamilton, Ont., "Creosoted Wood Block Pavements"; J. Duchastel, engineer, City of Outremont, P. Q., "Brick Highways and Streets"; W. Huber, engineer, Ontario Highways Department, "Maintenance Systems"; W. H. Connell, chief of the bureau of highways, Philadelphia, "Maintenance Materials and Methods"; Frank Smith, consulting engineer, New York, "Bituminous Macadam, hot mix, using asphaltic binder"; Prof. A. H. Blanchard, Columbia University, N. Y., "Bituminous Macadam, hot mix and penetration methods using tar binder"; Major W. W. Crosby, Baltimore, "Drainage and Foundations"; Elmer Thomson, Auto Club of America, "Motor Traffic, its trend and effect"; Col. W. A. Sawyer, chairman of the Massachusetts Highways Commission, "Different Types of Development used under various traffic conditions."

One of the subjects to be discussed will be the construction of an Imperial Highway as a memorial to the Canadian soldiers who are fighting overseas, while a resolution on the subject of the necessity of a uniform system of road maintenance will be brought forward. Delegates from the East will be interested in the discussion of a proposed highway from Quebec to Campbellton, and in the opening up of a new road between Ste. Agathe des Monts and St. Donat de Montcalm.

The Significance of "Graphs"

As civilization advances there is, from time to time, vividly brought to the attention of engineers the constantly increasing volume of comparative figures and general data of a scientific, technical, and statistical nature; and the need of a coherent and concise means of arranging this enormous mass of information in a form which will enable the average individual to recognize the salient features of these facts and which will serve as a guide in making correct deductions instead of accepting ready-made conclusions is increasingly evident. One of the most valuable instruments in the hands of the man who desires to boil an amount of information down to a point where its import can be gathered at a glance or be understood by minds which have not been specially trained to grasp the significance of figures is a simple and convenient system of charts, curves and graphs.

Mr. F. H. Martin, in his talk before the Manitoba Branch of the Canadian Society of Civil Engineers, printed in this issue, discussed at some length the value of such a system to the engineering profession. According to Mr. Martin, graphs are merely a "picturization of facts"—that is, statements or results are represented by diagrams or figures to picture or convey information in a vivid and instructive manner. Charts may be classified as "maps of results or facts," and statistics as "a collection of numerically tabulated facts."

The graphical analysis of all these results and facts gives a much clearer insight into their value and allows the average individual to apply them to the solution of what would otherwise appear to be complex problems. Mr. Martin will, in a later issue, discuss the mathematical phase of this system.

Large Expenditures on Toronto Schools

The management committee of the Board of Education of the city of Toronto have decided to recommend the expenditure of some $600,000 in providing a new high school and making necessary additions to many public schools at various points in the city where the overcrowding situation has become acute. The committee feel that this is the smallest possible sum that will be needed unless the work of the Board in providing adequate facilities for the school-children of the city is to be hampered. The chief item of expenditure will be a new central collegiate to be built on Bloor Street east, opposite St. Paul's new Anglican church, and which will take the place of the present Jarvis Street Collegiate; the cost of this building is placed at $250,000. The balance of the money will be spent on adding fifty-six additional class-rooms at an estimated cost of $6,000 per room; equipment will also be added to a number of the schools for domestic science and manual training.

Montreal Brickmakers Encouraged

The Financial Times prints an encouraging article on the attitude of Montreal brickmakers toward the outlook for the coming season. Building possibilities in and around Montreal show indication of a healthy recovery, though a fly in the ointment is likely to be the shortage of skilled labor. The general feeling is that the trade has reached rock bottom, and that the accumulated building which has been delayed must, some of it at least, be proceeded with during 1916. It is felt that many fine residences will probably be undertaken by men who have made money through munition orders of various kinds, and these represent no small proportion of the population of the city. The article closes: "Already the Street hears of some very large undertakings for the coming season. It is stated that the Imperial Oil Company will build a mammoth plant at Longue Pointe. Contracts are understood to have been let for the building of the new St. Maurice paper plant below Three Rivers, Que. This week the Government announcement was made that the Imperial Munitions Board had selected a site in Verdun for a $325,000 shell and fuse plant. The next six weeks will probably see the start of other notable building enterprises, though for the most part, as yet, it must be admitted that the architects' offices are practically idle."

Edmonton Branch C. S. C. E.

The Edmonton Branch Canadian Society of Civil Engineers had the pleasure of entertaining Mr. F. C. Gamble, Engineer of Railways for the British Columbia Government and immediate past president of the Canadian Society of Civil Engineers, at a dinner given in his honour at the Macdonald Hotel on the 9th instant. Mr. Gamble was stopping over in Edmonton a few days en route to Victoria, B. C., from Montreal, where he has been attending the Annual Meeting of the Society. The branch chairman, Mr. A. T. Fraser, District Engineer of the Canadian Northern Railway, presided at the dinner, which was attended by about twenty members of the Society resident in Edmonton.

Large Sum for Roadways

A committee of the York County Council have recommended to the Council the improvement of 210 miles of roads at a cost of some $750,000. The roads affected by the improvements are known as "Vaughan, Weston and Kennedy roads, and Yonge street, all running north and south.

This is the most comprehensive scheme drawn up since the good roads legislation was passed by the Ontario Legislature. In view of the heavy war expenditure placed on the county this year, the committee will recommend only a beginning in 1916. The road dealt with is likely to be that portion of Yonge street lying between Toronto and Lake Simcoe.

Discuss Elevator Construction

The Calgary Branch of the Canadian Society of Civil Engineers held its second dinner of the season at the Alexandra Hotel at 6.30 p. m., February 3, 1916. About 70 members and guests were present. After the dinner Mr. C. D. Howe, Chief Engineer, Dominion Government Grain Commission, addressed the Society on the subject of "Government Elevator Construction." His address was fully illustrated with lantern slides. It was listened to with much interest by the members present and a general discussion followed. The Calgary Branch expects to be favored with an address by Mr. J. G. Sullivan, Chief Engineer, Canadian Pacific Railway Company, on the Rogers Pass Tunnel, at an early date.

Fireproof Building Materials

Municipal authorities in Colon, Republic of Panama, have established a strict supervision over the building materials used in rebuilding and repairing the areas devastated by fire in the early summer. Colon, since it was first founded, has been built almost exclusively of highly inflammable materials and devastating fires have marked the years as it grew. Only four years ago one of these, more virulent than the rest, ate through the heart of the city, and again last spring another conflagration reduced nearly the entire city to a heap of ashes. At last the authorities have taken stringent measures to obviate the necessity for periodic re-building of the city. As a result the products which meet the stringent requirements set up by the authorities are doing a maximum business and among these are the H. W. Johns-Manville Company, who report that they were deluged with requests for immediate delivery. Orders for four car-load lots of the corrugated asbestos roofing alone, shipment from factory to be made within ten days receipt of the order, were accepted by the company on the spot.

Canadian Society of Civil Engineers

At a special meeting of the Toronto Branch held on Friday, February 18th, the subject of the reorganization committee was again discussed. Two of the nominees chosen at the last meeting, Messrs. G. A. McCarty and J. R. W. Ambrose, withdrew their names, and Col. R. W. Leonard was nominated for the Committee. The nominations for this Committee now stand as follows:—Messrs. G. R. G. Conway, H. E. T. Haultain, J. G. G. Kerry, E. W. Oliver, of Toronto; A. F. Macallum of Hamilton; S. B. Clement, North Bay; and Col. R. W. Leonard of St. Catharines. Prof. C. H. McLeod, Montreal, Secretary of the Society, was present and gave a short address and answered several questions of interest to the members.

Why Not "Pebbles"?

If the crimes against concrete practice could be classified, no doubt the majority of them would be listed in the column set aside for faulty aggregates.

An examination of standard dictionaries, textbooks in which definitions of materials may be found, and of specifications, will show a wide variation of practice in defining sand, gravel and boulders. Some dictionaries define gravel as a material free from a content of rock particles below a certain dimension, while others consider such particles as in part composing gravel.

Definitions fail to be uniform in fixing a line of demarcation that limits particles of gravel to certain maximum and minimum sizes; also in suggesting the cleanliness and uniform grading that standard specifications recognize as essential to coarse aggregate for concrete work. Confusion of "authorities" allows gravel to consist of particles ranging from 1-10 of an inch in smallest dimension to rocks or boulders.

Specifications no doubt owe their existence to a necessity compelled by faulty and conflicting definitions; yet good as the best specifications are, they do not always impress concrete workers with the fact that "gravel" means something entirely different from ungraded material coming from a natural bank deposit.

There should be no excuse for variations of individual interpretations. But as such variations exist, there is urgent need that the idea of maximum and minimum sizes for the particles of coarse aggregate be, if possible, expressed by a word which will also suggest the necessity for preparing the material to insure cleanliness as well as uniform grading. One word seems to have been overlooked, a word which takes one away from the thought of fine material, suggests cleanliness, and conveys an idea of limitation as to maximum and minimum sizes.

Pebbles, in the minds of most people, are clean rock particles made so by attrition in streams or otherwise. If in specifying gravel as coarse aggregate, "pebbles" ranging from a certain minimum to a certain maximum were specified, the idea of cleanliness and freedom from particles below and above certain sizes would be implied at once. Such material being unobtainable in a natural deposit would necessarily have to be prepared by screening or washing, or both, thus rendering the material fit for use as coarse aggregate.

Why "gravel"? Why not "pebbles"?—Cement Worker.

The Chemistry of Portland Cement

A research to determine the Chemical Constitution and Best Method of Producion of this All-important Building Material

By G. A Rankin*

Portland cement is now amongst the most valuable of manufactured products, its aggregate value being probably only second to that of iron and steel. Forty years ago its use was limited and it was manufactured on only a small scale; at the present time its use is so widespread that the annual production in this country alone is about 100,000,000 barrels. The chief use of Portland cement is as a substitute for stone. In some respects, concrete is superior to stone as a building material but under many conditions it is not so durable as the best building stone. There is reason to believe, however, that it may be possible to produce a cement which will yield a concrete of much greater durability than the Portland cement now made does. Indeed, as the demand for Portland cement has increased and as the requirements of engineers have called for material of better quality, the manufacturers have been able to meet these demands and to improve continuously the quality of their product. Now, it is to be noted that this continuous improvement has been brought about almost entirely by improvements in the mechanical appliances and methods of the industry, and owes very little to new ideas of how to make Portland cement based on a knowledge of what the constitution of the product really is.

Constitution of Portland Cement

The following pages present the results of an investigation of the constitution of Portland cement clinker and of the cementing value of the several constituents; these results enable us to indicate the nature and direction of the research work now required to ascertain the composition and best mode of production, of the cementing material best adapted to any particular purpose.

Portland cement clinker is the result of chemical combinations of the three oxides, lime, alumina, silica; but beside these three—which are the essential components—two others, namely, magnesia and ferric oxide, occur to some extent in commercial cement. The average of a large number of chemical analyses of American-made Portland cement is, according to Meade,

CaO	62.0 per cent.	Fe_2O_3	2.5 per cent.
Al_2O_3	7.5 per cent.	MgO	2.5 per cent.
SiO_2	22.0 per cent.	SO_3	1.5 per cent.

From this it is evident that more than 90 per cent. of an average Portland cement consists of the three oxides, CaO, Al_2O_3, SiO_2; one would expect, therefore, that its properties are due mainly to the presence of the above three components and that the relatively small admixture of the other oxides exerts at most a wholly secondary influence. Indeed, it has been shown that good Portland cement can be made from the three pure oxides, lime, alumina and silica, in the proper proportions.

Now, ordinary chemical methods enable us to ascertain the aggregate proportion of each oxide present, but they yield us no information as to the manner in which these oxides are combined with one another—in other words, as to the substances which actually are present in the clinker and are responsible for its characteristic properties. The determination of this question is very important, for this reason; that, until we know what these substances actually are, we cannot hope to improve the method of making Portland cement, or to improve the quality in any desired direction, except by cut-and-try methods; and it is generally recognized that such empirical methods are much less certain, and take a vastly longer time to reach the goal. than methods based on a real knowledge of the factors in the problem. The determination of this question has been the object of a very large number of investigations; but the experimental basis of most of this work has been altogether insufficient to decide the several questions at issue. There has been, in general, a failure to realize the fact that a system so complicated as this can be solved only by proceeding systematically, using as a guide the principle known as the phrase rule and establishing definite criteria for the recognition of the several substances which occur.

Cement Clinker

Cement clinker is a mixture of substances of very similar properties, and is, moreover, exceedingly fine grained, as a consequence of which it is a matter of some difficulty to make quantitative determination of the constituents; but this difficulty can be surmounted by studying separately each of the presumable constituents of the clinker and determining definite values of certain properties which serve to characterize it and to distinguish it from other possible constituents. Accordingly the first problem is to isolate and determine all the possible compounds of lime, alumina and silica which we may expect to find in Portland Cement clinker, to establish their relations at high temperatures and to ascertain their optical characteristics which constitute the most convenient and satisfactory criterion of the identity of the several substances.

These characteristic properties of the several solid substances, containing only CaO, Al_2O_3, SiO_2, which are likely to occur in Portland cement have been determined at the Geophysical Laboratory of the Carnegie Institution of Washington in the course of a systematic investigation of all compounds formed when any mixture of these oxides is heated to a high temperature. In American-made Portland cements the relative proportions of these oxides vary only between comparatively narrow limits: CaO-60 to 64; Al_2O_3-5 to 9; SiO_2-19 to 25; in other words, in considering this special problem we have to deal with a very restricted portion of the field of the whole system CaO-Al_2O_3-SiO_2.

The Ternary System CaO-Al_2O_3-SiO_2.

In order to work out this system completely it proved necessary to investigate about 1,000 different mixtures of these three oxides and to make about 7,000 heat treatments and microscopical examinations of the resultant products. Each such mixture, which was always made up of especially pure materials, was alternately fused and ground to a fine powder, the fusions being made in a platinum crucible to avoid con-

*Before American Concrete Institute Convention.

tamination, in order to obtain a thoroughly combined product. Each of these products was heated in an electric furnace, the temperature of which was carefully controlled and measured, until all changes had ceased, when it was quickly chilled; and the resultant material was subjected to a complete optical study. This procedure, which was carried out systematically,

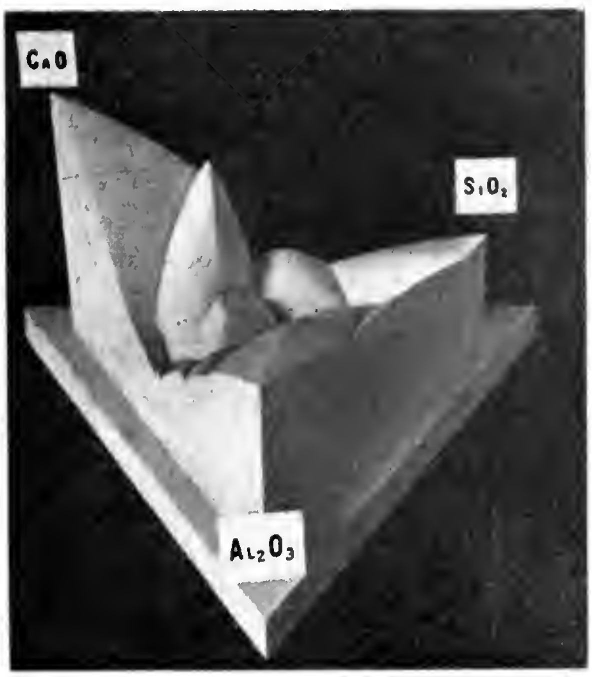

Fig. 1—A Model of the Concentration-Temperatures by the Ternary System.

enables one to determine the crystalline phases present at temperatures ranging from that at which melting begins to that at which the charge is completely melted; and thus to ascertain the melting temperature and optical properties of all compounds of lime, alumina, silica which form when any mixture of these three oxides is heated.

Data Plotted

The data thus obtained can be interpreted most readily if they are plotted in three dimensions; the concentration (composition) of each mixture is represented by a point within an equilateral triangle* on the horizontal plane, the magnitude of the corresponding temperature by the distance above this plane. It would lead us too far to go into details of the construction and properties of such a model; suffice it to say that the series of surfaces thus described represent the melting temperatures of all products obtained when any mixture of the three oxides is heated progressively to higher and higher temperature. A photograph of such a model is reproduced in Fig. 1. As can be seen from the photograph, the model resembles a relief map of a mountainous region: each mountain peak is the melting point of a pure component or of a pure compound; the mountain slopes represent the melting temperatures of a component or compound in ternary mixtures; the points where the rivers in the valleys meet to form a lake are the lowest melting temperatures, known as eutectic points. This model, when interpreted with the aid of the principles underlying such equilibria, enables one to specify the order in which the several crystalline substances will form when any mixture composed entirely of lime, alumina and silica is heated, and also to state what are the final products when the reactions have gone to completion.

Let us consider the crystalline substances which will form when a mixture composed only of these three oxides in the proportions such that they will produce a good Portland cement, is heated. For this purpose a diagram such as Fig. 2 is useful. This diagram is a projection on the horizontal plane of that portion of the solid model necessary for our present purpose. The corresponding temperatures are here represented by isothermal lines, which are completely analogous to the contour lines on an ordinary map. In this diagram the group of dots represents mixtures of CaO, Al$_2$O$_3$, SiO$_2$ from which Portland cement of good quality can be made.

This group of dots, it will be noted, are all included within the triangular area formed by lines connecting the compositions of the three compounds, tricalcium silicate, dicalcium silicate and tricalcium aluminate. For that reason, if any mixture of CaO, Al$_2$O$_3$ and SiO$_2$, such as is represented by one of these dots, is heated so that all chemical reactions are completed, the final product obtained will be made up of the above three compounds.

Characteristics of Constituents

The constituents of Portland cement clinker made up only of the oxides CaO, Al$_2$O$_3$, SiO$_2$ are therefore the three compounds 3CaO.SiO$_2$, 2CaO.SiO$_2$ and 3CaO.Al$_2$O$_3$. Each of these compounds has optical properties peculiar to itself which serve to distinguish it from the rest. The several characteristic optical and crystalligraphical properties were obtained by a study of each compound itself. These values are constants for the individual compounds in all mixtures made up from pure CaO, Al$_2$O$_3$ and SiO$_2$; i. e., the

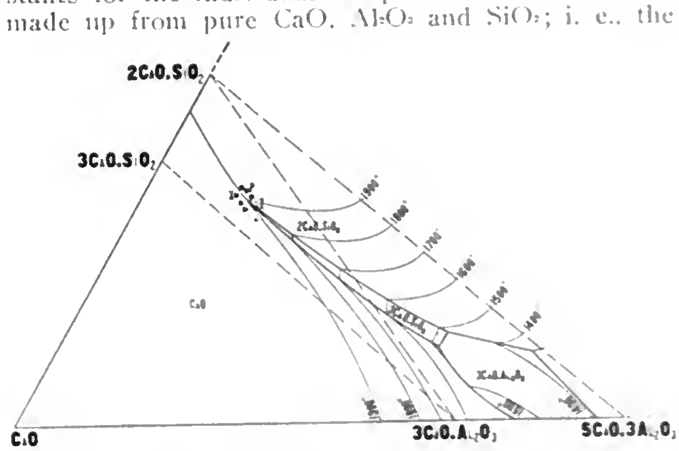

FIG. 2.—PROJECTION OF A PORTION OF CONCENTRATION-TEMPERATURES OF TERNARY SYSTEM CaO-Al$_2$O$_3$-SiO$_2$ WITH ISOTHERMALS.

The dots represent the mixtures of CaO, Al$_2$O$_3$ and SiO$_2$ from which Portland cement of good quality can be made

final products resulting when such mixtures are heated, are present as individuals of constant optical properties and not as solid solutions.

Microscopical examination of commercial Portland cement clinker shows it to be made up largely (over 90 per cent.) of these three compounds 2CaO.SiO$_2$, 3CaO.SiO$_2$ and 3CaO.Al$_2$O$_3$. It would appear, therefore, that the value of Portland cement as a cementing material when mixed with water is largely due to one or more of these compounds. Before taking up the cementing value of each of these compounds, however,

*In such a diagram, the pure components CaO, Al$_2$O$_3$, SiO$_2$, are represented by the apices of the triangle; the binary system, CaO-Al$_2$O$_3$, CaO-SiO$_2$ and Al$_2$O$_3$-SiO$_2$, by the sides of the triangle, and ternary mixtures by points within the triangle.

let us consider their formation when Portland cement is burned.

Chemical Reactions

For this purpose let us follow the reactions which take place when a mixture whose composition is CaO (as $CaCO_3$) 68.4 per cent., Al_2O_3 8.0 per cent., SiO_2 23.6 per cent. (point P, Fig. 2), is slowly heated. This mixture, made up only of the pure oxides, lime, alumina, silica, when properly burned, will produce a good Portland cement. When such a mixture is heated, the first change is the evolution of the CO_2; the lime then unites with the other components to form the compounds $5CaO.3Al_2O_3$ and $2CaO.SiO_2$ (both of which form readily) probably in the order named, since the former has a lower melting point than the latter; subsequently these two compounds unite in part with more lime and the compounds $3CaO.SiO_2$ and $3CaO.Al_2O_3$ appear. This formation of the last two compounds—a process which goes on very slowly in mixtures of their own composition—is materially facilitated by the circumstance that in the ternary mixtures a portion of the charge has already melted and promotes reaction by acting as a flux or solvent. The temperature at which this flux first appears is 1335 degrees C.. the eutectic temperature for the three compounds $2CaO.SiO_2$, $5CaO.3Al_2O_3$, $3CaO.Al_2O_3$. As the temperature of burning gradually rises above 1335 degrees, the relative amount of flux increases and the rate of formation of $3CaO.Al_2O_3$ and $3CaO.SiO_2$ increases correspondingly. At a temperature somewhat above 1335 degrees the compound $5CaO.3Al_2O_3$ will have completely melted in the flux and the formation of $3CaO.Al_2O_3$ is complete. The substances present as crystals at this stage are $3CaO.SiO_2$, $3CaO.Al_2O_3$, $2CaO.SiO_2$ and free CaO. Of these the $3CaO.SiO_2$ is rapidly increasing in amount, due to combination of $2CaO.SiO_2$ with CaO, while the amounts of solid $2CaO.SiO_2$, CaO and $3CaO.Al_2O_3$ are all decreasing, the $2CaO.SiO_2$ partially by combination with CaO and partially by dissolving along with $3CaO.Al_2O_3$ in the flux. As the temperature is raised still further, the amount of flux (liquid) increases and the rate of combination of CaO with $2CaO.SiO_2$ to form $3CaO.SiO_2$ increases. But it is not necessary to raise the temperature until the charge is completely melted, as normal cement clinker is obtained at temperatures much below complete melting; in other words, the necessary reactions will go to completion below the temperature required for complete melting. The rapidity with which the reactions go to completion is governed by the temperature and by the amount of flux formed at that temperature. The requisite amount of flux in turn depends upon the fineness of the raw materials, since the finer these materials are ground the more readily the components will combine. For finely ground raw materials of the above composition, composed only of CaO, Al_2O_3, SiO_2, a temperature of about 1650 degrees C. is required for burning. At this temperature the clinker would be about 30 per cent. melted and 70 per cent. solid crystalline material. a proportion of flux which would admit of the necessary reactions going to completion in a reasonable time. The charge will always completely crystallize on cooling; the percentage composition (based on actual data) of the clinker thus obtained would be approximately $3CaO.SiO_2$. 45 per cent.; $2CaO.SiO_2$, 35 per cent.; and $3CaO.Al_2O_3$, 20 per cent. The melting temperature of the flux necessary for the production of the clinker is materially lowered by the pressure of small amounts of impurities; that the small amounts of Fe_2O_3, MgO, etc., in commercial cement actually have this effect is shown by the fact that the temperature required for burning is about 1425 degrees C.

Table I.—Compositions and Burnino Temperatures of Various Portland Cements.[1]

Percentage Composition of Clinker.

Portland Cements	Actual Components.	Relative to Content of $CaO\text{-}Al_2O_3\text{-}SiO_2$.	Burning Temperature, Deg. C.	Constituents of Resulting Cements.

White (A)	CaO .... 66.2 Al_2O_3 .... 6.4 SiO_2 .... 25.0 } 97.6 MgO, Fe_2O_3, Na_2O and K_2O 2.4	CaO ... 67.9 Al_2O_3 .. 6.5 SiO_2 ... 25.6	1525	$2CaO.SiO_2$ $3CaO.SiO_2$ $3CaO.Al_2O_3$ } Small amount of CaO.
Gray (B)	CaO .... 63.2 Al_2O_3 .... 7.7 SiO_2 .... 22.4 } 93.3 MgO, Fe_2O_3, Na_2O, K_2O and SO_3 .... 6.7	CaO ... 66.7 Al_2O_3 .. 9.0 SiO_2 ... 24.3	1425	$2CaO.SiO_2$ $3CaO.SiO_2$ $3CaO.Al_2O_3$ } Small amounts of $5CaO.3Al_2O_3CaO$ and ferrites.

[1] The data given in this table are based largely on the work of this laboratory. The analyses of commercial clinkers are from publications from the Bureau of Standards and from "Portland Cement," by R. K. Meade. The temperatures of burning and the constituents given are based both on our work and that of the Bureau of Standards.

In the foregoing discussion, we have followed to completion the course of the reactions which take place when cement clinker composed of pure CaO, Al_2O_3, SiO_2, is burned; in other words, we have shown the formation of the compounds during the burning of mixtures of these three oxides in the proper proportions for cement clinker, and stated what compounds will be present in the final product if the burning is continued long enough and at a sufficiently high temperature.

This description of the essential reactions which take place when cement made up only of CaO, Al_2O_3, SiO_2 is burned, applies equally well to commercial Portland cement. In commercial cements, however, there is always present small amounts of Fe_2O_3, MgO. alkalies, etc. These minor components. which total less than 10 per cent., have but little effect on the major constituents of the clinker. During the burning of cement clinker, however, these minor components play an important part, since their presence ensures the formation of a flux at a much lower temperature, and thereby materially promotes the combination of CaO with Al_2O_3 and SiO_2.

Burning Temperatures

In order to afford a comparison of the chemical compositions, the temperature required for burning and the final products obtained for different types of Portland cement, the necessary data have been collated in Table I. The examples given in this table are based on the average for a large number of analyses of each of three types of Portland cement, viz., pure cement, made only of CaO, Al_2O_3, SiO_2; commercial white cement; and the more common gray variety of Portland cement.

If the raw material for pure cement is perfectly burned at a temperature of 1650 degrees, the clinker obtained will consist of the three compounds—orthosilicate of lime, tricalcic silicate, and tricalcic aluminate. The example of a pure cement, given in Table I. has the chemical composition 68.4 per cent. lime, 8.0 per cent alumina, 23.6 per cent. silica. The raw material for white commercial cement, when burned at a temperature of 1525 degrees. will produce a clinker which consists largely of the same three compounds found in pure clinker, except for a small amount of free lime. The average chemical composition of this type of cement as given in the table is 66.2 per cent. lime, 6.4 per cent. alumina, 25 per cent. silica, and 2.4 per cent. magnesia, iron oxide and alkali. The clinker obtained on burning the raw material for commercial gray cement at 1425 degrees will consist largely of the same three compounds found in the other two types of clinker, except for small amounts of free lime, the compound $5CaO.3Al_2O_3$, and iron oxide as ferrites. The composition of this clinker is 63.2 per cent. lime, 7.7 per cent. alumina, 22.4 per cent silica, 6.7 per cent MgO, Fe_2O_3, alkali and SO_3.

(To be continued)

Cushions for Block Type Pavements

Introduction of Sand-Cement Cushion Due to the Need of Making the Cushion an Integral Part of the Pavement

By Maurice B Greenough*

The word cushion is defined as anything introduced to relieve the shock or jar between parts. Its use in paving practice represents the application of a word which was originally of popular significance only to a highly specialized engineering function. As used in highway practice, then, a cushion is that material introduced between the bottom of the wearing surface and the top of the artificial base in pavements whose surface is of a type represented by wood, asphalt, brick, or stone block. The nature of the filling material between individual blocks has no bearing upon the use of the term, but serves to accentuate some of the properties ascribed to the cushion. According to the definition and to accepted practice, the primary function of the cushion in pavements of the block type is to relieve the shock of moving loads on the surface of the pavement. Other functions may be attributed to the cushion; to provide a firm and uniform support for individual blocks; to compensate for irregularities in the surface of either the base or the blocks composing the surface, and finally to transmit the effects of surface loads to the artificial base with a uniform distribution of intensity.

Sand Cushion

A variety of materials have been used for cushions at one time or another, but sand alone or in combination with other materials has enjoyed the widest application for this purpose. Local availability of stone dust or granulated slag has determined their use in a number of instances, but stone dust is similar to sand in its physical characteristics and properties and granulated slag may approach a condition similar to that obtained by the use of cement in the cushion. Bituminous materials have been used to some extent, particularly in wood block construction, but more for the purpose of waterproofing the bottom of the blocks than for providing an elastic cushion.

Sand-Cement Mixtures

Wood block pavements have been laid upon a sand cushion for many years, but within the last decade a mixture of sand and cement has superseded plain sand to a large extent. Asphalt blocks have been laid upon a sand-cement cushion through the necessity of providing a firm and uniform support for blocks having so large an exposed area in proportion to the depth. Up to 1913, sand was almost universally used as the cushion material for both brick and stone block pavements, and it is only since that time that sand-cement mixtures have been employed to any great extent, and in some cases that it has been dispensed with entirely.

Greater Intimacy

During the time that cushions have been in use there have been two important and indicative tendencies developing that are worthy of attention. They are, the increasing emphasis laid upon the necessity of securing a uniformly dense degree of compactness, and the gradual reduction of cushion thickness. The origin of both these tendencies lies in a desire to obtain greater intimacy between individual grains in the cushion and between the surface and base of the pavement as a whole. An unconfined mass of sand cannot be said to possess elasticity, the property which must be developed to make a satisfactory cushion. The minimum elasticity of sand exists when a multitude of particles are in the free state and the maximum obtains when those particles are bonded in the form of sandstone or even pure quartz. Therefore, we may say that the degree of elasticity that can be developed by sand is directly proportional to the intimacy of contact between individual grains or to the extent of its confinement. It is true that each grain may possess elasticity, but it may be overshadowed and rendered unavailable by the lack of intimate contact. Most specifications for sand cushions seek to secure maximum density by laying stress upon spreading and rolling, irrespective of any consideration as to the possibility of ever producing a dense cushion with any amount of rolling in view of the granulometric composition of the sand.

Depth of Cushion

In early practice, cushions for both brick and stone block pavements were as deep as three inches. There has been a gradual reduction in depth until now we find most brick pavements laid upon cushions from 1 to 1½ inches deep, and cushions for stone block pavements are usually limited to a maximum of two inches. Where sand is still used as the cushion material for wood block pavements, one inch is the common depth. One-half an inch is the customary depth for the mortar cushion of wood and asphalt block pavements. Doubtless the reduction in thickness of pavement cushions has been brought about, in part, by smoother surfaced concrete bases. The intricacy of the cushion problem depends upon the nature of the joint filler in the pavement surface. If the individual blocks composing the surface are free to move without affecting their neighbors, the effect of surface loading is localized to that portion of the cushion underlying each block. It is only when the blocks in the surface are bonded to form a monolithic slab that the elastic function of the cushion reaches its maximum importance.

*Presented before section D of the American Association for the Advancement of Science at the Columbus meeting.

and it is in this connection that so much discussion has recently arisen.

Pavements as Engineering Structures

The time has come when we should look upon a pavement as an engineering structure and approach its problems from the same angle that we approach other engineering problems, namely by methods of exact analysis, based upon the fundamental laws of mechanics. That the problems of pavements are more complex than those of other engineering structures does not prevent the possibilities of an ultimate solution. This complexity of elements has simply inhibited the development of an exact analysis, not prevented it. The stresses to which pavements are subjected arise from two sources, the loads of traffic and thermal changes. Under the latter may be grouped all the stresses which are due to thermal conditions accentuated by the presence of moisture. Stresses may be set up at any time which arise from a single source or they may be created by combined traffic and thermal forces. An analysis of pavement stresses predicated the fact that a structure is inherently weak whose component parts are not so arranged as to meet stresses from both sources in the most advantageous manner. For the purpose of analogy a pavement subjected to traffic load may be compared to an arch composed of metal plates connected by rivets. In this case, the plates are subjected to direct tension, compression, or shear; the rivets are subjected to bending and shear. In this analogy, the grout between individual blocks may be compared to rivets, whose function it is to transmit the stress from one unit to another. While the rivets may be subjected to a true bending stress in the transmission of stress between plates, the grout between blocks in a pavement does not carry direct bending, since the flexure of a pavement surface produces compression in the joints above the neutral axis and tension below. It is further called upon to resist the impact of moving loads upon each block which introduces the element of shear.

Foundation Support

An incident came to the attention of the writer recently in which the rear wheels of a loaded truck weighing about twelve tons, proceeding at a rate of about eight miles an hour, broke through the surface of a four-inch cement grouted brick pavement laid upon a natural earth foundation, brought about probably by lack of foundation support. The accident served to confirm an opinion that we are working with a very narrow margin of safety in our grouted block pavements as far as shearing resistance is concerned, in view of the fact that we cannot always be sure of adequate support for pavement surfaces.

A series of experiments conducted at Case School of Applied Science showed that the ultimate shearing resistance of a four-inch brick perfectly grouted with a 1:1 mixture of sand and cement is approximately 17,800 lbs. In the case of the truck mentioned we may assume that the load was distributed in the proportion of one-third to the forward axle and two-thirds to the rear axles, making the load upon one rear wheel about 8,000 lbs. The tires on the rear wheels of the truck were of the caterpillar type, so that it is reasonable to assume that the load would have been transmitted to individual blocks with impact. The pavement was quite smooth on the surface so that on the principle of mechanics that a suddenly applied load produces double the equivalent of a gradually applied load both in the load itself and in the intensity of the stress developed, the probable load exerted upon the blocks in this pavement was 16,000 lbs., as a minimum estimate. The ultimate load of 17,800 lbs. was obtained with a perfectly grouted joint, that may or may not have existed in the case under discussion.

Elastic Resistance

The logical conclusion to be drawn from this illustration is that unless the blocks in the surface of a grouted pavement are adequately supported, stresses may be set up in the joints far in excess of the safe limit. If the pavement is constructed with a cushion on an artificial base, it is the function of the cushion to provide such a support and to contribute its elastic resistance, both of which prevent an undue stressing of the joint filler. There is a limit to the elastic deformation that a pavement may undergo and retain its integrity.

Surface Deflection

The passage of a vehicle over a pavement produces a deflection in the surface which is distributed over a wide area. When the surface of a pavement is depressed by loads, the work performed in any given instance is the measure of the resiliency. When the internal stresses created are within the elastic limit of the structure, or within the range through which the deformation has a constant relation to the stress, the amount of the elastic energy stored and recoverable is equal to the resiliency. If, however, the elastic limit of the structure is exceeded, some of the applied energy is dissipated in the form of heat. In the former case, the structure will resume its normal position upon removal of the load, but in the latter there can be no recovery and there exists a permanent deformation.

Elasticity of the Structure

It must be remembered that in pavements of the block type, with the exception of wood and perhaps asphalt, the materials involved are only slightly elastic, and when combined in the form of a pavement, the elasticity of the structure as a whole depends upon the integrity of bond between the various elements. Therefore, it is essential that there should be a slight relief for applied loads, in order that the stresses created may build up slowly, otherwise the pavement may be subjected to stresses that are of double intensity due to impact alone, which may be augmented by further impact stresses caused by irregularities in the surface. We may say, then, that to successfully withstand heavy loads, the elastic properties of all the elements of the pavement should be brought into play, and to produce this condition the elements should act in harmony.

Cement-Cushion Inherently Stronger

Thus we find the introduction of the sand cement-cushion for block pavements to have been caused by a desire to make the cushion such an integral part of the pavement that there should be no chance of losing energy needed to successfully bear heavy moving loads. The presence of the cement assures a cushion of uniform density, and one that can perform all the functions ascribed to cushions in general, leaving nothing to chance. Not only is the cushion inherently stronger, but it stiffens the whole structure by its complete bond to the surface and the base. In such a pavement, the natural relief against suddenly applied loads is found in the sub-grade itself, and the possibilities that any one element of the structure will be overburdened are lessened.

Effect of "Roughs" on Brick Industry

Present stringent situation in the face-brick industry—Due to the temporary craze for rough-faced brick—Manufacturers to blame

By T. P. Cuthbert*

The vogue of rough texture brick, particularly during the last three years, has brought about an almost complete revolution in the business, and it is the object of this paper, by considering the effect that this change has had on the men who make and the men who sell face-brick, to cast a little light, if possible, on what we may expect from rough texture brick in the immediate future.

Who Started the Fashion?

Six or eight years ago we frequently heard the question asked—"Who started the use of rough texture brick?" I don't think that question has ever been satisfactorily answered, but we all know that it got its real start about that time and we know that a great deal of money was expended by both face-brick manufacturers and dealers everywhere in establishing this demand. And this was not alone through the use of printers' ink, but more particularly by dealers in the laying up of very elaborate panels of "rough brick" in their display rooms, each trying to outdo the other, and apparently with but small regard for expense.

The Additional Cost of Displays

The total amount expended in this way, owing to the frequent changes in displays necessitated by changes in the texture of brick, must have been enormous. And if we add to this the money that has been spent in laying up special panels of texture brick for the individual inspection of special customers, the total amount would actually run into the hundreds of thousands of dollars.

This practice I believe goes a long way toward explaining why few dealers have made satisfactory profits during recent years, and also why so many of the older and more conservative dealers, some of whom may be said to have fathered the face-brick business in this country, express dissatisfaction with present conditions, for there were no such extraordinary expenses connected with the sale of smooth face brick.

Six or eight years ago, when only "good" rough texture brick were made, when quality was considered rather than price, they were probably profitable to both manufacturer and dealer. Since then, while the cost of selling has steadily increased, both price and quality have come in a straight line downward, until the profits once made on these brick have reached or passed the vanishing point, and the price obtained for smooth face-brick has been pulled down, along with the price for roughs.

Expected by the Older Dealers

Is there anything surprising about present conditions? It would seem not. We are getting just exactly what we should have expected and what some of our oldest face-brick dealers actually anticipated. When you take a well made face-brick, wire-cut the face, scratch it up into a so-called rug or otherwise mutilate it, you destroy the very qualities that make it a face-brick; it loses its class, and becomes an absorbent dust and dirt catcher. While on the other hand, if a common brick is treated in a similar manner, its crudeness and the imperfections that identify it as a common-brick fit only for backing-up, are covered, and it is elevated to a point where "rough texture" face-brick and "rough texture" common-brick reach a common level, and where both sell (or soon will sell) for about the same price.

This means an extra profit for some of the scores of common-brick manufacturers, who have been boosted into the face-brick business by this craze for rough texture brick; but it spells nothing less than ruination for many of the best known men in the face-brick business—the "Fathers of the Industry."

By the roughening process, the improvements that have been made in face-brick during the last two generations, as well as the expensive equipment on many face-brick plants in all sections of the country, are neutralized and made of little or no account.

Demand for Face Brick Growing

Some have been inclined to explain these conditions by a general fall-off in the demand for face-brick, or to depressed general business conditions, but this is not correct; it is a fact that the percentage of buildings, particularly houses, in which face-brick have been used, has rapidly increased during recent years, and the demand for face-brick has shown a corresponding increase in spite of general business conditions.

Shipments of face-brick in this country have actually increased almost 33 per cent. during the last six years and the largest three years we ever had, with one single exception, have been the last three. Nor can we give rough texture brick the credit for being responsible for this increase, at the very largest year the face-brick business ever enjoyed was 1909, when rough texture brick made up a very insignificant part of the total.

Prices Dwindle in an Upward Market

The business of most face-brick manufacturers has shriveled up, not because of general business conditions, but because of the craze for rough texture brick. But this is not all of it—it is not even the worst of it. The average price of all legitimate face-brick made in this country, whether smooth or rough texture, has come in a straight line downward, purely and simply as the result of the influence rough texture brick have had on the business, and in spite of the fact that the price of practically every other manufactured article has gone in a constant, straight line upward.

The tendency of common-brick for the last six years has been upward, with prices at their very best during the last two years. The average price obtained for paving-brick for the last six years has increased constantly until the end of 1914, the increase from 1909 to 1914 being approximately thirty-two per cent., and 1914 was the best year in the history of the paving-brick industry.

While the price of everything else has gone up and is still going, the prices we have obtained for our product have been going down, and we have not the

* Before the American Face-Brick Association.

slightest reason for supposing that they have struck bottom.

Bad Business for the Industry

What excuse was there for this craze for "rough texture brick"? To my mind there was very little. We will all grant that there are certain jobs where rough brick seem to fit and with climatic and other conditions taken into consideration, they are a good business proposition for the home builder or investor. No one admires such buildings more than I, for even a log house, or a bungalow built of cobble-stones looks good in some locations—if the architecture fits the material. But we don't find the lumber dealers trying to create a foolish fad for log-houses.

In Pittsburgh a few years ago rough faced brick were used in a house on a shady avenue and immediately adjoining it the same builder also used smooth brick of the same shade. I saw these houses while they were going up and after they were finished, and it was almost impossible even for a man in the face-brick business to see any difference between the two brick, even from across the street. These houses are now about six years old—one job is of a greasy appearance and extremely dirty while the other presents almost exactly the same appearance as it did when finished. Cases that parallel this can be found in all sections of the country. It makes no difference whose rough texture brick is considered and it makes no difference whether they are made on common-brick plants or on face-brick plants, the story is the same; they get dirty, and if they are soiled and dirty at the end of a very few years what will happen to them in ten or twenty years?

How Many Manufacturers are Ahead

Leaving the future out of the question for the moment, how many face-brick manufacturers and dealers are ahead of the "rough brick" game? And, if we are not ahead of it now, what can we expect from it in the future, in view of present common-brick competition? We are making our rough face-brick in exactly the same textures as the common rough-brick makers, and some of us are paying 25c per M. for the privilege of doing it.

Do we have to stand for this common-brick competition? I think not, for there is still one kind of brick that common-brick manufacturers cannot imitate, and that is a good brick,—with a good, smooth face.

The Chicago Clay Show

About four years ago, practically every important manufacturer of face-brick was called upon to contribute to a fund for the making of elaborate brick displays in the Coliseum during the big clay show; in spite of the fact that most manufacturers were then chiefly interested in smooth face-brick, many factories making them exclusively, every important display of face-brick, including all of the prominent panels, all ornamental brick walls, gate ways, and even the "model" brick house, were laid up exclusively with rough texture brick; not a single important display of smooth face-brick was made. Practically all of the architects, builders, and dealers in face-brick in the Chicago district during, and for two or three years after the clay show, were rooting exclusively for rough texture brick. They and brick people elsewhere talked "art" in rough texture brick until they persuaded themselves that all of the art in architecture began and ended in wire cut face-brick.

And what was the result? They accomplished what seemed impossible and brought about a complete revolution in the face-brick business; and I know that I am not overstating the facts when I say that more, much more than seventy-five per cent. of all face-brick used in Chicago since the clay show have been roughs.

The Effect Upon Prices

Since the clay show, prices obtained for face-brick in the Chicago district have come tumbling down like a house of cards, and the quantities of legitimate face-brick that have been shipped into the Chicago district this year, whether rough or smooth, have been cut in half, the big half now going to the concerns who, previous to the clay show, were manufacturers of common-brick.

Have our friends the brick dealers been benefited by the craze for roughs? I am in a position to know that many of them have not, for I have discussed the matter with a great many dealers during the past few months. Many of them are old established concerns whose names are known to all of you, and they, without exception, have expressed dissatisfaction with the conditions that have been brought about by rough texture brick. Several of them expressed their intention of openly opposing the sale of rough texture brick this year, and of instructing their salesmen accordingly.

Can brick dealers bring their business back to the old footing by pushing the sale of smooth texture brick? I believe they can; in fact it has already been done in one of our largest cities.

The rough brick craze which started in Philadelphia was suddenly and effectually stopped, with the result that the average price now obtained for face-brick in that city is higher than in any other important eastern city, and the profit per M. is, also, correspondingly high.

What has been done in Philadelphia, can be done elsewhere. In sections where rough texture brick are the fad, the manufacturers and dealers started the demand by trimming their windows, so to speak, with rough texture brick. But no expensive displays would be necessary to bring smooth brick back to their former popularity, for a comparison drawn between smooth and rough texture brick walls which have been standing for a few years will serve all purposes most admirably.

Buildings Themselves the Best Arguments

The smooth face jobs have, for the most part, remained clean, but the rough texture jobs that have aged a little, now resemble autumn leaves grown old.

In my opinion one of the best ways to kill off common-brick competition is for manufacturers of face-brick, particularly manufacturers of red face-brick, to make smooth face-brick in all the varying shades in which they have been making rough face-brick, including the flashed brick with red cores and blue and brown edges and other markings, and for them to make them as smooth and perfect as possible.

Such a brick will lend itself to artistic bricklaying quite as well as a rough texture brick of the same shade. The principal difference between the two brick will be that the smooth brick will have a better and cleaner cut appearance in the wall.

A brick wall built of hard burned, smooth face-brick will stand the test of time and is the best possible advertisement for brick, just as the poorest possible advertisement is a brick job that is ruined by soot and dirt, as most of the rough brick jobs in the country will be in a mighty short time.

The Organization of a Maintenance and Repair System on Ontario Roads

By A. A. Smith

A valuable paper on the organization of a maintenance system was read by Mr. A. A. Smith before the recent Toronto Good Roads Conference. The following points from Mr. Smith's paper were unavoidably omitted from our last week's report of this Conference:

There is a wide distinction between Maintenance and Repair as applied to highway operations. The operations required to constantly oppose the deterioration of a completed road by the effect of traffic and climatic conditions, and to keep it as nearly as possible in its initial condition, constitute maintenance. Without maintenance, the road tends to deteriorate and the operations necessary to restore it constitute repairs. Both processes are often similar in kind and may even overlap. A well constructed road properly maintained should not need repair for some time, but a properly repaired road always needs maintenance.

All the railroads have adopted a strict maintenance system on their road-beds, bridges, culverts, etc., which has proven of the greatest value. This maintenance system should prove equally beneficial in the case of highways.

There are several schemes for highway maintenance that have been adopted. One is to assign to a certain individual a given length of road, credit him with a certain sum, and leave him to his own devices in its upkeep. This method does not usually give best results. Another method is to have one man over a larger area and give him sufficient means to maintain it. This man usually gets a gang of men and teams together and does his share all at once, when the farmers are slack—which again means that during the balance of the year, when traffic is heaviest, the road gets no attention at all. A third method is the patrol system, after the kind adopted in New York State which appears to be a most satisfactory method for maintaining roads. The patrol man, supplied with tools and machinery from the municipality, is employed continuously to maintain from five to ten miles of road. His work consists in preventing unnecessary deterioration of the road surface, in the removal of loose stone, the repair of the centre of the road due to the wear from horses' feet, sanding the road and supplying binder in wet weather to prevent ravelling, cleaning out gutters, culverts, catchbasins and waterways, lowering the shoulders of the road, repairing damages due to wash-outs and freshets on all slopes, and making any necessary repairs on wood floors of culverts and bridges. He should report once a week on the location and nature of each day's work to a highway foreman or inspector. This foreman should have sufficient knowledge and experience to justify spending his entire time in supervising, planning, and setting out the work. This foreman is given a certain area or section, for the maintenance of which he is held directly responsible. This area generally covers from sixty to one hundred miles of roadway, with from eight to ten patrol men under the foreman. The foreman shall not have the power to engage or discharge any patrol man without first reporting to the superintendent, but otherwise shall have full control over them. The foreman is required to report weekly to the superintendent on the work done, time spent, materials used, and the need of larger necessary repairs, such as resurfacing, rolling, oiling, and repairs to bridges, culverts, etc., which are to be done under the supervision of the superintendent.

The duties of the road superintendent in connection with road maintenance are similar to those of a municipal clerk,—reporting to and carrying out the instructions of the council. He shall attend all meetings of the council which relate to work carried out by him, and shall supervise all work and employ inspectors or foremen as may be required, who shall also be subject to dismissal by him. He shall employ and discharge any patrol men, teams, or laborers required to carry out the work, and purchase all necessary material and tools. He shall keep an accurate record of men and teams employed, work done, material used, and furnish an O. K. pay-sheet account to a proper committee for their approval before the municipal treasurer issues any checks in payment thereof. The superintendent must pay the foreman and men under him in accordance with the time sheets and obtain a receipt for the same.

One of the chief difficulties in the maintaining of macadam roads is, perhaps, ravelling of the stone in dry weather when the road has not sufficient binding material. One method of alleviating this trouble is, by sprinkling the road with water where water is convenient and plentiful, or by applying a thin coat of sharp clean sand or screenings thoroughly tamped. Another evil is the tendency for the road to rut, due to a greater wheel load than the road is capable of carrying, inferior binding material, and the tendency of a team to follow the wheel-tracks of the preceding vehicle. The best remedy for this is to loosen the stone in and around the depressions and fill them in with new material of the same size and quality, tamp well, leaving the surface slightly higher than the surrounding surface in order to allow for compaction.

Dust prevention is a necessity in prolonging the life of a macadam roadway. Dust can be overcome by watering, sweeping, or by the use of oil. Proper maintenance of a road cannot be carried out without the use of a roller. This should be used in the spring of the year, when the road is soft and pliable. Ditching is also a big item in maintenance work. All ditches need constant attention. They should be kept free from weeds, grass and rubbish, and given sufficient fall to carry water off immediately. This patrol system wherever used, has been found to give good satisfaction; it keeps the road in good repair in all seasons.

Western Railway Building

An interesting announcement was recently made in connection with the Dunvegan and Fort McMurray railway now under construction north of Edmonton by the J. D. McArthur Co. 340 miles of railway north of Edmonton are to be ballasted this year. Plans are being prepared for a big steel bridge over Peace River at Peace River Crossing; this will include a traffic deck and the total cost will be about three-quarters of a million dollars. The building of the bridge will enable the line of the Central Canada Railway Company to be continued westward one hundred miles, guaranteed by the provincial government.

Fifty miles already are constructed to Peace River Crossing and the remainder—fifty miles—has been located to the Waterhole district.

By the end of the present winter the total mileage will be as follows:

	Miles.
E.D. & B.C. main line to Spirit River..	357
Grande Prairie branch	60
Central Canada from McLennan to Peace River	50
A. & G. W.	250
Total mileage	717

These roads all were built under the guarantee policy of the provincial government and run through districts that were badly in need of railway facilities.

Mr. McArthur also announced that the Northwest Lumber Company, of which he is president, is cutting 25,000,000 feet of lumber this winter, about 350 men being employed. A cut of 10,000,000 feet is being made near Lac la Biche and another cut of 15,000,000 feet near Sawridge. The mills at West Edmonton will reopen about the middle of March.

Progress on Breakwater, Victoria, B.C.

During 1915 work on the breakwater at Ogden Point, Victoria, B. C., has progressed so rapidly that the structure, which, at the beginning of the year, was not visible above the surface of the water is now two-thirds finished. The breakwater is composed of three arms, the first extending only 330 ft. from shore, the main arm having a total length of 1,500 ft., and the outer arm which will be 700 ft. long. On Jan. 1 the work had been completed for a distance of 1,630 ft. from shore. Over 1,000,000 tons of coarse and fine rubble have been used in the construction thus far, it is reported. J. S. Maclachan, Dominion government engineer, has given out the following figures referring to total quantities thus far handled on this contract: Coarse rubble dumped, 792,415 tons; core, or fine rubble dumped, 241,925 tons; granite blocks placed in position 93,279 tons; concrete poured, 20,883 cu. yd. During 1915 273,000 tons of rubble stone were deposited, 75,000 tons of granite blocks placed and 19,000 cu. yd. of concrete poured.

Mr. Jones Prophesies Good Year

At the annual meeting of the Canada Cement Company, held in Montreal, on February 15, Mr. F. P. Jones, vice-president, stated that an entirely new plant had been erected for the making of munitions, and that the two orders received—one for machining and the other for manufacturing steel and forgings for machining—would keep them fully running until the end of the year. He believed this year's sales of cement would be larger than during 1915. Cities and municipalities could not use less cement during the coming season than they did last year, and were now in a better financial position to carry on improvements. In addition to this all the large Government works, including the Welland Canal, would be continued.

Reinforced Concrete Buildings

In a paper on "Interesting Features of Reinforced Concrete Buildings In and Around Montreal," read at a meeting of the Canadian Society of Civil Engineers, Montreal, Mr. C. M. Morssen, of the Atlas Construction Company, gave a description of cracks in concrete walls, outside finish, winter made concrete, and the adaptability of concrete to complicated structure. As an instance of the latter he referred to St. Michael's Church, corner of St. Urbain and St. Viateur Streets. This building has no columns and is built of plain and reinforced concrete. The basement ceiling is carried by flat arches 54 ft. clear span, having a raise 30 in. The arches are 18 ft. centre to centre and connected with a flat slab 7 in. thick. The main auditorium is covered by a dome, which is carried by four full centre arches, each 52 in. diameter, and by four consoles, which arches and consoles are carried down to rock by four strong tower abutments. The dome is about 118 ft. above the sidewalk and 110 ft. above the auditorium floor.

The outside walls are covered with Greendale brick and terra cotta; the dome and roofs, however, are finished in concrete, the dome having received a colored waterproof cement finish about an inch thick, showing green shamrocks on a white field. The green color was obtained by mixing a green pigment with the ordinary cement and the white color was secured by the Atlas white cement. The main cupola is carried on a series of semi-circular arches fixed rigidly into a heavy ring of concrete reinforced with steel bars in the front of circular hoops. There are 12 semi-circular arches, which are 36 in. deep, 12 in. wide at the bottom and 6 in. wide at the crown. At the crown the arches are connected by a disc 4 in. in diameter and 36 in. deep. Each arch carries 1/12th of the load on the cupola and its own weight.

For the computing of the stresses in the concrete and steel the total weight of the cupola, including suspended ceiling, wind, snow, etc., was taken at 150 pounds per square foot. The twelve semi-circular ribs are reinforced with four one in. twisted bars, two near the top and two near the bottom, and connected with stirrups about every 12 in. The cupola, which is of a uniform thickness of 5 in., is reinforced with 1/2 round bars at 6 in. centre to centre.

Mr. Morssen briefly described the method by which the stresses were ascertained. He stated that the cupola was first designed without ribs and of a uniform thickness of 8 in. following the theory given by E. Collignon, "Cours de Mecaniques," p. 631. This theory is that in a spherical cupola the stress in the material used are independent of the thickness of the cupola and are determined only by the diameter of th cupola and the specific gravity of the material used. With hoops made of 1/2 sq. bars and placed at 9 in. centre to centre the stresses in the steel and concrete would be kept within the safe limits. The thickness of the cupola will be rather governed by the stiffness to be attained than by the safe stresses. However, taking into consideration the large proportions of the cupola it was decided to provide 12 ribs as described, and making the assumption rather more severe than the actual conditions warranted, the stresses in the steel and concrete were kept within the safe limits. As built the cupola is about 40 per cent cheaper than a Gostavino tile cupola and about 50 per cent. cheaper than a steel structure fireproofed with concrete or tiles.

A half spherical cupola at the rear with a diameter of 52 feet, and a small 20 foot cupola at top of the tower are of uniform thickness, and are reinforced with hoops made of round half-bars. The four main arches carrying the cupola, the cantilevers, and the arches in the basement were designed on established methods. The winding stairs and the large windows were made of reinforced concrete, although no established formulae were available.

High Level Reservoir, New Westminster, B. C.

The city of New Westminster, with the completion of the new high level reservoir capable of serving a population of at least 80,000 persons, have realized their ambition of many years' standing to possess an entirely modern waterworks system. The new reservoir was completed in November 1915, construction work having occupied approximately a year. It is situated adjacent to the old reservoir on the highest point within the city limits and, together, they now

Discharge Chamber of Reservoir, at New Westminster.

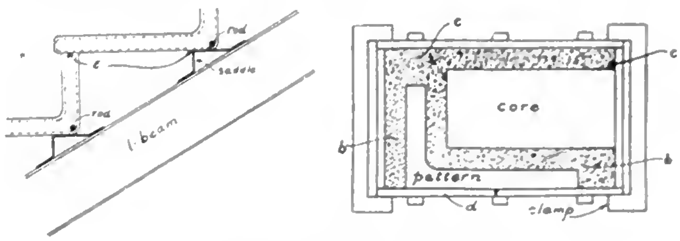
supply the whole area with water. The new reservoir has a capacity of 42,000,000 gallons.

Coincident with the construction of the new reservoir the embankment of the old high level reservoir was raised, adding 500,000 gallons to its capacity. The total capacity of both reservoirs is now 8,900,000—approximately seven days' supply for the present population. The minimum discharge from the 25-in. main is 6,250,000 gallons per 24 hours, with a maximum discharge of 7,000,000 gallons under high-water level on Lake Coquitlam. The 14-in. main has a minimum discharge of 600,000 gallons, with a maximum of about one million. The reservoir was designed by Mr. J. W. B. Blackman, city engineer, at an estimated cost of $40,200, and was built under his supervision with the assistance of superintendent Ankers.

The Commissioners of the Transcontinental Railway have issued their 11th annual report, covering the fiscal year ending March 31, 1915.

Sand Molds for Concrete Steps

In certain classes of work it becomes convenient to use a process of sand casting, for an irregular concrete form which is to be repeated over and over again. The way this is done is in all respects analogous to the casting of iron. The wooden pattern used to prepare the mold in sand is handled in exactly the same way as the pattern for a metal casting. The sketch in Fig. 1 shows how separate sections of the step are placed upon the steel structure which supports them.



Step mold and method of erection.

The molding is a simple matter, the pattern is placed upon the drag (d), Fig. 2 and sand is then rammed all around it (b) within the flask. A hollow wooden core, placed at one side of the flask as shown, makes it unnecessary to use large quantities of sand, and what is more important, largely reduces the weight to be handled. Sand is then rammed up around the top (cc), and the top board put in place and clamped.

The whole thing is then turned upside down with the aid of a small jib crane. Upon removing the drag (d), and the wooden pattern, the form is ready for the insertion of reinforcement in the same way as a mold for an iron casting is completed by the insertion of cores.

Wire cloth with a good-sized mesh is used, as shown in dotted lines in Fig. 1, with a single twisted rod at one corner, as indicated. The cement used is the proportion of 1:2:4, small-sized stone being required because of the small space into which the concrete has to be poured.

The hard packed sand gives a finish to the concrete steps which is final. Nothing more remained to be done in preparing them for erection, with the exception of a little smoothing in some cases at the points (e) at which they come in contact with each other and with the steel structure.

The under side of the step as erected is the surface which is free to the air when cast. Any irregularities appearing in it are hidden by the way in which the steps are erected—Concrete.

A two days' convention of the Canadian Fairbanks-Morse Company, Limited, was recently held in Montreal. The convention was attended by heads of departments, salesmen, and representatives of firms in Canada and the United States whose goods are handled by the Canadian Fairbanks Morse Company. The representatives of these concerns spoke at the convention along the lines of familiarising the heads of departments and salesmen with the various goods. At a banquet held in the St. James Club, Mr H. J. Fuller, the president, referred to the large number of men in the company's service who had volunteered for overseas. Mr. Graham Drinkwater, vice-president; Mr. C. W. Wiggin, manager of the Montreal branch; and Mr. C. J. Brittain, manager of the Winnipeg branch, also spoke.

Stresses in Lattice Bars of Columns

By W. W. Pearse, C.E.

Explanatory

The Editor, Contract Record:—

I send you herewith a discussion on the stresses in lattice bars of columns.

In the Engineering Record of November 2, 1907, I published an article on the same subject, in which I gave a formula for the transverse shear as follows:—

$$R = \frac{232\ A\ r}{n} \quad \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Where A = area of column,
r = radius of gyration, axis parallel to back of channels,
n = distance from neutral axis to extreme fibre.

Equation (1) was based on the New York law for columns, as follows:

$$\frac{P}{A} = 15{,}200 - 58\frac{l}{r} \quad \ldots\ldots\ldots\ldots (2)$$

Now if the American Railways Engineering Association's formula is used, which is

$$\frac{P}{A} = 16{,}000 - 70\frac{l}{r} \quad \ldots\ldots\ldots\ldots (3)$$

$$\text{Then } R = \frac{280\ A\ r}{n} \quad \ldots\ldots\ldots\ldots (4)$$

This value given in equation (4) is what has been adopted by several authorities.

It will be noticed that the length (l) does not appear in either equations (1) or (4).

Now, referring to equations (2) and (3), if we put $l = 0$, the quantities $58\frac{l}{r}$ and $70\frac{l}{r}$ drop out and there is no stress to be deducted due to the bending of the column

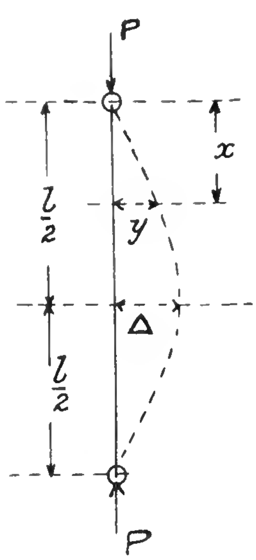


Fig. 1.

or, in other words, as the length of the column approaches zero, the stress to be deducted due to the bending also approaches zero. There is a much greater stress in the column due to bending when the column is long; it is only the stress caused by the bending of the column that causes any stress in the lattice bars.

Referring to Table 1 of the discussion I send you, it will be noted that the stresses for different lengths vary. Columns that are 9 ft. long have much less stress in the lattice bars than columns that are 20 ft long.

It is also evident for the same reasons cited above that the value .0251 given for the transverse shear in Bulletin No.

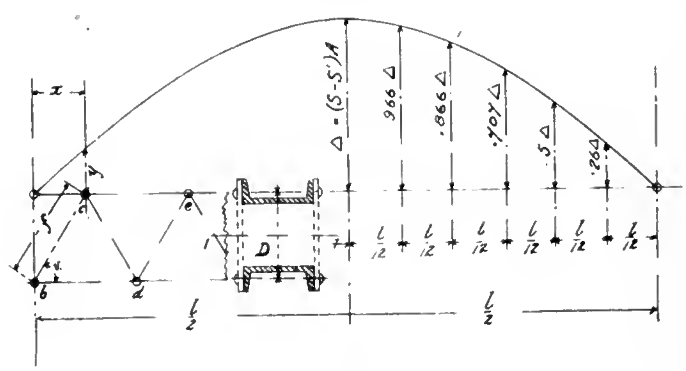

Fig. 2.

44 of the University of Illinois must only be true for values of ratios $\frac{l}{r} = 37.8$ or thereabouts, and you will notice by referring to my Table that for values of 37.8 for $\frac{l}{r}$ my formula agrees very closely indeed with the tests.

For columns that are fixed top and bottom an entirely new discussion and table would have to be worked up along the lines outlined in my discussion.

In conclusion would say that of course there are stresses caused by imperfections in fabrication, etc., that no formula could ever cover.

Yours truly,
W. W. PEARSE,
City Architect and Sup't of Buildings.

Toronto, Feb. 5.

Stresses in Lattice Bars of Columns

The stresses in lattice bars of columns have always been considered, at best, a very rough approximation.

Euler's column theory is universally accepted as a correct analysis of the subject. The following discussion of the stresses in lattice bars is based on the same theory of bending in columns and should be equally as correct.

In Merriman's Mechanics of Materials, 1894 edition, page 115, he gives for Euler's formula, for the resisting of columns, the following equation:—

$$y = \triangle \sin.\ n\,\pi\,\frac{x}{l} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

If it is assumed that the column is hinged top and bottom and a load P is applied, then under these conditions, $n = 1$ and equation (1) reduces to,

$$y = \triangle \sin.\ \pi\,\frac{x}{l} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

See Figure 1.

Let l = length of column in inches.
A = area of column in square inches.
S = safe stress per sq. inch (very short columns).
S' = safe stress per sq. inch (long columns).

Then $(S - S')A$ = total stress due to bending at centre of column.

If equation (2) is plotted assuming l as any length of column in inches, and divided into twelve equal parts, the ordinates shown in Figure 2 will be found and will apply in all cases. If for $\triangle$ we substitute $(S - S')A$, we will get the stress strain curve in the column due to bending of column.

Referring again to Merriman's Mechanics of Materials, 1894 edition, he gives the following column formula:—

$$S^1 = \cfrac{Sc}{1 + \cfrac{Sc}{m \pi^2 E} \times \cfrac{l^2}{r^2}} \quad \ldots\ldots\ldots\ldots\ldots (3)$$

Substituting usual values for the different quantities in equation (3) we get,

$$S^1 = \cfrac{16000}{1 + \cfrac{1}{12000} \times \cfrac{l^2}{r^2}} \quad \ldots\ldots\ldots\ldots\ldots (4)$$

Referring to Figure 2, y = stress* in channel due to bending of column in panel bd. Therefore the stress in lattice bars be is equal to y sec v. There are two lattice bars be so

$$\text{stress in each bar be} = \frac{y \sec v}{2} \quad \ldots\ldots\ldots\ldots (5)$$

But the angle v is usually taken at 60 degs. and the secant of 60 degs. is 2,

Therefore the stress in the lattice bar be = y .... (6)

As the stress in the lattice bar be is a maximum, all that it is necessary to do is to design one lattice bar for the end panel and make the balance of the bars the same length and area. Each end lattice bar would have to be designed to act as a column having a length equal to f and a load equal to y.

Referring to Bulletin No. 44, University of Illinois, page 47, they give a formula for lattice bars as columns based on actual tests:—

$$\frac{P}{A} = 21400 - 45 \frac{l}{r} \quad \ldots\ldots\ldots\ldots\ldots (7)$$

Equation (7) gives the ultimate fibre stress per square inch.

*It should be noted here that this whole stress is taken up by one channel when the axis of bending is parallel to back of channels, for when the column bends one channel will be plus and one channel will be minus, and it is only the plus side that adds any additional stress to the column, and it is this stress that must be deducted from the carrying capacity of the column due to bending.

Length of Col. in feet.	Size of Channels.	D = Distance C.C. of rivets perpendicular to the flange.	A = Area of Col. in sq. inches.	r axis 1-1,	l/r	S' = Safe load per. sq. inch	(S - S') = Stress per sq. inch to be deducted due to bending	x	f = 2x for an angle of 60°	y = Stress in end Lattice Bars, in lbs.	Stress in end Lattice Bars according to tests in lbs.	Section of Lattice Bars required.

Table 1

Therefore the safe load would be:—

$$\frac{P}{A} = 6600 - 45\frac{l}{r} \quad \ldots\ldots\ldots\ldots\ldots \quad (8)$$

Equation (8) is using a factor of safety of 3¼, which is about the same as is given in equation (4).

Referring now to Figure 2, it will be noticed that the y ordinate for the end panel, right hand side, is .26 △ or very nearly half that found for the second panel, which is .5 △, this shows that the curve is very nearly a straight line at each end. Assuming that it is a straight line, the following analysis may be made:—

Referring to Fig. 3 we get the following:—

$$\text{Tan } z = \frac{.26\,\triangle}{\frac{l}{12}} = \frac{3.12\,\triangle}{l} \quad \ldots\ldots\ldots\ldots\ldots \quad (9)$$

Therefore $y = x \tan z$.

$$\text{or } y = \frac{3.12\,\triangle\,x}{l} \quad \ldots\ldots\ldots\ldots\ldots \quad (10)$$

If for △ we substitute $(S - S^1)$ A, equation (10) becomes

$$y = \frac{3.12\,(S - S^1)\,A\,x}{l} \quad \ldots\ldots\ldots\ldots\ldots \quad (11)$$

Equation (11) will give the stress in end lattice bar be,

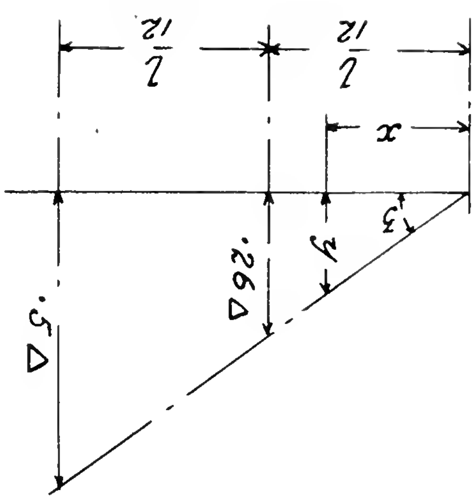

Fig. 3.

which will always be a maximum. Value for S^1 must be found by equation (4) or any other column formula that may be desired to find the safe load per square inch of column.

From equation (11) Table No. 1. was figured, which gives the stress in the end lattice bars for channel columns having lengths of 9 ft., 12 ft., 15 ft., 18 ft., and 20 ft. For intermediate lengths it would be safe to interpolate. For different areas it will be directly proportional to the area, as will be seen by referring to equation (11).

In figuring Table I. the values D, A, r, and x were taken from Cambria Steel Company's Handbook, see Fig. 2.

If the angle v is not 60 degs. then equation (11) will become,

$$y = \frac{3.12\ (S - S^1)\ Ax}{l} \cdot \frac{\text{sec. } v}{2} \quad \ldots\ldots\ldots\ldots\ldots \quad (12)$$

which reduces to,

$$y = \frac{1.56\ (S - S^1)\ Ax}{l}\ \text{sec. } v. \quad \ldots\ldots\ldots\ldots\ldots \quad (13)$$

Note:—Equations (11) and (13) are only true for the end panel.

Now to prove that equation (11) and (13) are correct and agree with experiments, refer to Bulletin No. 44, of the University of Illinois, page 33, supplementary to Table 6, where it gives in the last column of the table,—ratio of transverse shear to compression load = .0251. This was the result of tests on column marked 1. By referring to page 10 of the Bulletin 44 a full description is given of Column No. 1:—A = 18.76; L = 21 ft.; $\frac{l}{r} = 37.8$; angle of lattice bar with axis of column = 63 degs. 30 mins.

It seems reasonable that all columns having a ratio of $\frac{l}{r} = 37.8$ or thereabouts and having the lattice bars sloping approximately 63 degs. 30 mins. should have a ratio of transverse shear to compression load = .0251. Referring to Table No. 1 herewith it will be noticed that for two 15-in. channels at 33 lbs., 20 ft. long, the stress given in the end lattice bar is 4060 lbs. $\frac{l}{r} = 42$, which is reasonably close to what is given in the tests to give approximately the same results. Therefore we get for transverse shear the following, where A = 19.8 and the compressive load per sq. inch = 13900 lbs.:

Transverse shear = 19.8 × 13900 × .0251 = 6880 lbs.

But there are two lattice bars,

Therefore $\frac{6880}{2}$ = 3440 lbs. transverse shear on each lattice bar, see Fig. 4.

The secant of 30 degs. = 1.155. Therefore 3440 × 1.155 = 3973 lbs. = stress in end lattice bar, which is very nearly what is given in Table 1, which is 4060 lbs.

Referring to Table 1 again, it will be noticed that for two 7-in. channels at 9¾ lbs., 9 ft. long; $\frac{l}{r} = 40$, $S^1 = 14200$ lbs. and stress in end lattice bar is 1160 lbs. And A = 5.7 square inches.

Therefore, transverse shear = 5.7 × 14200 × .0251 = 2030 lbs., and $\frac{2030}{2}$ = 1015 lbs. = transverse shear for each lattice bar.

Then 1015 × 1.155 = 1170 lbs., which is within 10 lbs. of that given in the formula, which was 1160 lbs.

Referring to Table 1., two 10-in. channels at 15 lbs., 12 ft. long, $\frac{l}{r} = 38$, $S^1 = 14300$ lbs. per sq. inch, A = 8.92 sq. inches, stress in the lattice bar = 1760 lbs.

Transverse shear = 8.92 × 14300 × .0251 = 3200 lbs.

Therefore $\frac{3200}{2}$ = 1600 lbs. transverse shear for each lattice bar. Then 1600 × 1.155 = 1848 lbs. stress in lattice bar, which is within 88 lbs. of what is given in Table 1.

Referring to Table 1, two 12-in. channels at 20½ lbs., 15 ft. long, $\frac{l}{r} = 39$, $S^1 = 14200$, stress in lattice bar = 2560

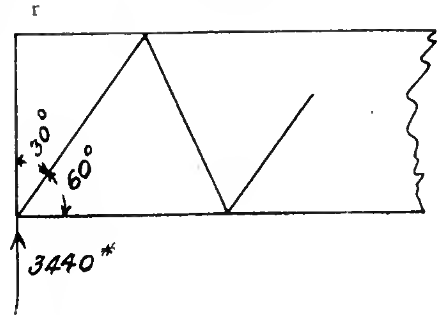

Fig. 4.

lbs., A = 12.06 sq. inches, transverse shear = 12.06 × 14200 × .0251 = 4300 lbs.

Therefore, $\frac{4300}{2}$ = 2150 lbs. transverse shear for each lattice bar. Then 2150 × 1.155 = 2480 lbs. stress in lattice bars, which is 80 lbs. less than Table 1 gives.

Referring to Table 1, two 15-in. channels at 33 lbs., 18 ft. long, $\frac{l}{r} = 39$, $S^1 = 14200$, stress in lattice bar = 3937 lbs., A = 19.8 sq. inches, transverse shear = 19.8 × 14200 × .0251 = 7060 lbs.

Therefore, $\frac{7060}{2}$ = 3530 lbs. transverse shear for each lattice bar. Then 3530 × 1.155 = 4077 lbs. stress in lattice bar, which is 80 lbs. less than Table 1 gives.

Sizes of lattice bars given in the last column of Table 1 were figured by equation (8).

The Practical Value of Curves

The Application of Curves, Charts and Graphs to Facilitate the Analysis of Engineering Problems and Statistical Information

By F. H. Martin*

The talk this evening can hardly be termed a paper—it is more in the nature of a resume or collection of curves and diagrams that have been found helpful, especially in preliminary design work, and they are described in the hope that they may be of value to some of you.

It was the intention originally to analyse the mathematical side of the art of curve plotting, but mathematical discussions are usually rather dry, so this phase has been omitted and may be taken up later in the season if desired.

The talk this evening will be confined to the practical values of the curves which will be shown after a few introductory remarks:

Graphs are statements of results presented by means of diagrams, geometrical figures, or pictures to delineate or convey information in a vivid, forcible, and instructive manner; to put it tersely, it might be termed a picturization of facts.

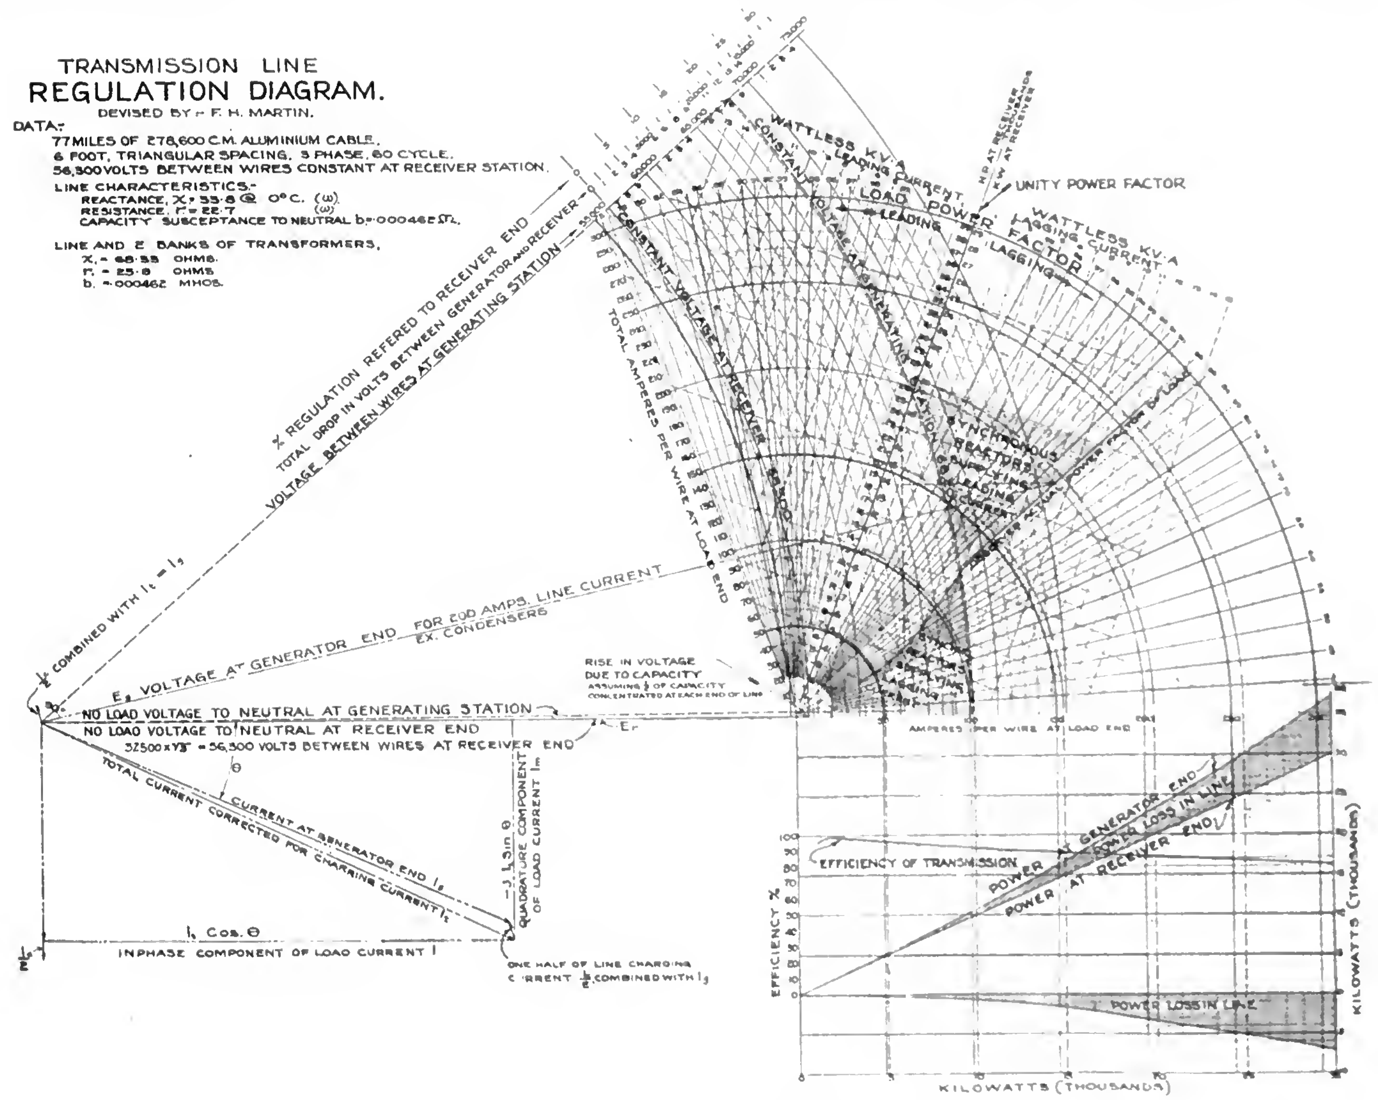
Charts are maps of results or facts, similar to, but slightly more complex, than graphs.

By reducing the value of facts to properly proportioned pictures or symbolic drawings, and arranging these geometrical diagrams in such a position that their relationship is apparent, their relative values, are instinctively appraised by the eye, and the lesson they are intended to teach, promptly and easily grasped.

Statistics are a collection of facts tabulated numerically, or, a group of facts brought out by collecting numbers; in other words, it is the science of measurements of the social organism.

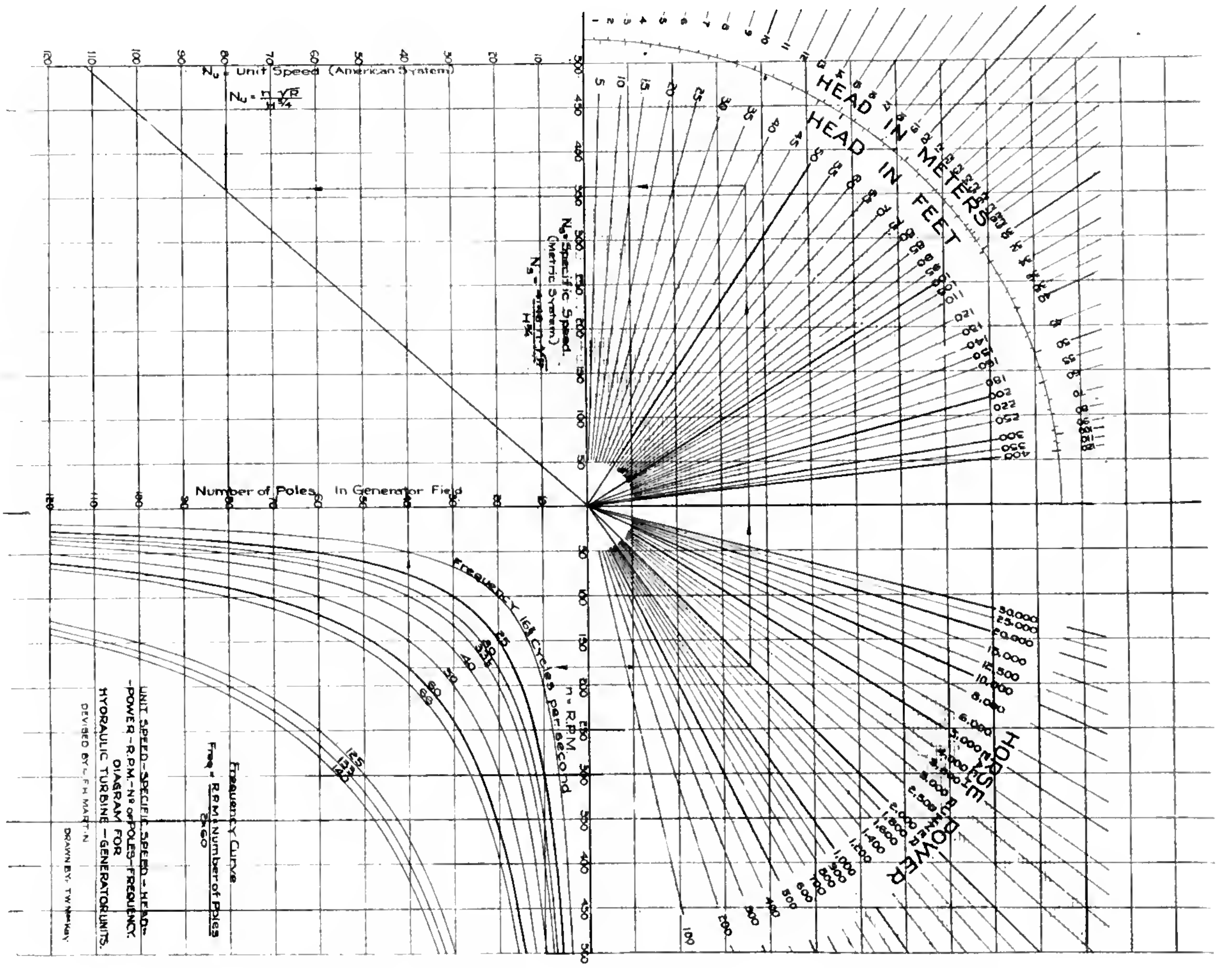
Each year thousands of dollars are spent in collecting all kinds of data, which is usually arranged in a tabulated form, and anyone who has ever had an occasion to analyze this enormous mass of information will have felt the need of a more coherent and concise means of arranging the same, in order to enable the average individual to recognize the salient features of these facts, and, to serve as a guide in making correct deductions therefrom, instead of accepting ready made conclusions handed to him.

If the average citizen, and, especially the business man who usually dodges the simplest charts, obsessed with the



Transmission line regulation diagram.

*Designing Engineer, Winnipeg River Power Company, before the Electrical Section of the Manitoba Branch of the Canadian Society of Civil Engineers.



Unit speed—Specific speed—Head—Power—R.P.M.—No. of poles—Frequency diagram for hydraulic turbine—Generator units.

idea that they involve higher mathematics, or, some other mysterious agency, knew how to interpret charts and curves, it would be feasible to elucidate to him in effective form those facts, relating to broad social and public improvements, public-service operations, and international, state or municipal affairs.

To the ordinary person this does not seem to be a matter of great importance, and at first sight we cannot see its relationship to engineering, but when we consider that during the five years that the French engineers labored on the Panama Canal, they lost 22,189 men, while America has lost 5,000 in twice that time, and has also succeeded in transforming the region from one of the most deadly to one of the most healthy localities on this continent, due largely to the praiseworthy efforts of Surgeon-General Gorgas, who recognized how potent in the reductions of the cause of those losses are sanitary environments and the separation of the infected from the sound, we see how essential it is to standardize all the facts that would influence an engineering project in such a manner as to permit just comparison being made and then analyze the results graphically so that correct deductions can be made. Then there will no longer be any excuse for acting in ignorance since the curves will show exactly what is happening so that all conscientious workers for social, sanitary and other reforms will be able to discover at once the direction in which it is most desirable to concentrate attention.

The two principal methods of elementary statistics which ought to be understood by all students or officials who handle figures, and, which are easily within the grasp of all independent of mathematical training, but which are generally misunderstood, or ignored by the uninterested or uninitiated, are, the method of averages, and the method of diagrams, or the graphic method.

When we deal with large and complex masses of figures, we are unable to grasp them in their entirety, however clearly they may be tabulated. A list of figures, as for instance, the population of different cities, the wages of numerous individuals, etc., becomes less comprehensive as its length increases. A list of ten numbers can easily be grasped, of twenty, only with an effort, even by the highly skilled reader, while a series of figures for one hundred successive years leaves hardly any impression on the mind at all—we cannot see the wood for the trees—and we find that this also holds true in all fields of endeavor.

As civilization advances there is being brought to the attention of the average individual a constantly increasing volume of comparative figures and general data of a scientific, technical, and statistical nature. The graphical method permits the presentation of such figures and data with a great saving of time, and also with more clearness than would otherwise be obtained.

If simple and convenient standards can be found and made generally known, and adhered to, there will be possible a more universal use of graphic methods, with a consequent gain to mankind, because of the greater speed and accuracy with which complex information may be imparted and interpreted.

The graphic method is also used in solving problems in every branch of engineering (which otherwise would involve very complicated or laborious mathematical computation) by drawing vectors to scale, and estimating slopes and arears under curves. This method not only gives the student a mental picture of the operation, but compels him to think of the relation between the various quantities involved, instead of merely performing operation by fixed rules, and the principles so illustrated are more deeply impressed.

Much of the work of calculation done by engineers or designers is in the repeated application of a limited number of formulas to a variety of different conditions, which involves merely the substitution of different variables in identical equations. Any mechanical means for performing this operation expeditiously will not only lead to a saving of time and mental wear and tear, but will also minimize the chances of error. Such a device is the calculating chart, or monogram, and the increasing frequency with which it is employed in the more recent publications, is a good evidence of the growing recognition of its value.

Many excellent examples of these charts have appeared of late years and are available for use, but it is evident that, to realize their full value as useful instruments, the engineer should have a sufficient acquaintance with their underlying principles to construct charts suited to his individual needs.

Some of the chart forms employed to-day have been known and used for many years, but it is only within recent times that any systematic study has been made of the subject as a whole, or any attempt to properly classify and correlate the different types.

In this work the French have been pioneers, and, it is to one of them, Maurice D'Ocagne, that we owe what is probably the most thorough and comprehensive text on the subject, his "traite de Nomographie." Soreau and others have also produced very creditable work on this subject.

Although books on Nomography have been published in many foreign languages, there does not appear to have been anything written on the subject in English, outside of a few scattered magazine articles, which have covered only restricted portions of the field.

Books in English on graphical calculus are by no means uncommon, but this is generally looked upon as something different from Nomography, although a strict line of demarcation between the two subjects would be somewhat difficult to trace.

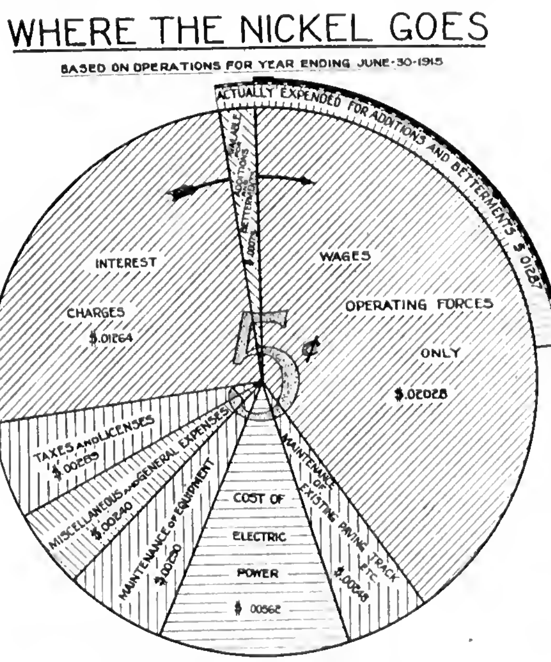


Diagram showing distribution of revenue.

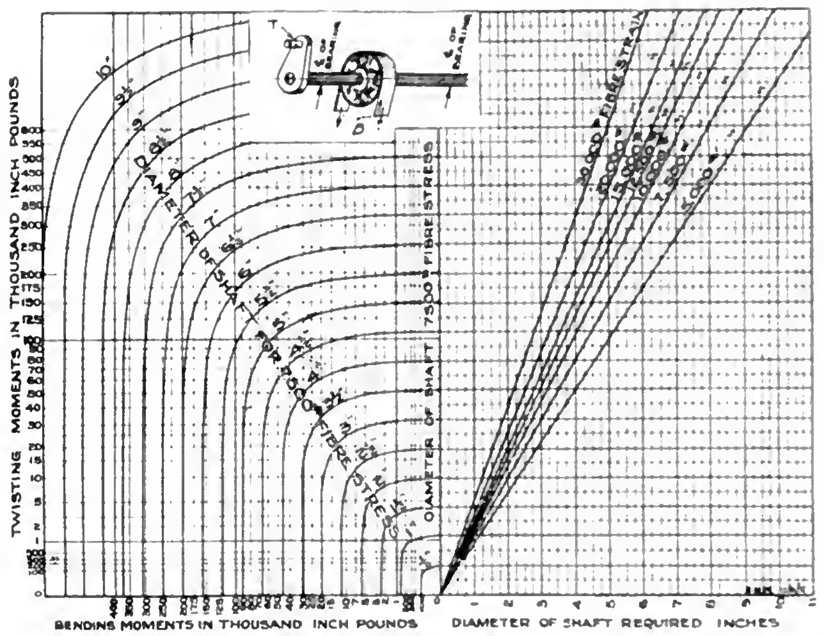

DIAGRAM OF STRENGTH OF ROUND SHAFTS, COMBINED TWISTING AND BENDING MOMENTS

Believing that this subject should be particularly useful to the practical engineer, who is often a trifle rusty in some parts of his mathematics, an effort has been made to simplify the mathematical treatment, and a series of problems has been worked out in detail, illustrating the application of all the chart forms herein explained.

It is thought that a study of these would afford a clearer insight into the methods employed, and a better understanding of the difficulties likely to be encountered, than would be possible from a purely theoretical analysis.

It will be observed that the corresponding metric dimensions have been added to the scales of some of the diagrams shown, this practically makes the charts international in character and like music, they may be arranged and interpreted in any language. This feature is greatly appreciated by engineering organizations whose scope is international and frequently saves considerable time in translating and converting from one system to the other.

The great advantage of the graphic method is that all of mankind's observations and calculations may be arranged or charted on co-ordinate paper, just as the hydrographer charts the position of the coasts, islands, rocks, channels, etc., on a chart, which is used to guide the mariner on his voyage, so the graphic method may be employed as a guide, especially for preliminary designs and estimates.

The prevailing tendency in engineering design is towards projects of greater magnitude containing a minimum number of units of maximum output, in making the initial layouts the approximate dimensions of the various apparatus must often be guessed at, and the uncertainty as to the exact requirements to be fulfilled by the work when completed is also a disadvantage, which cannot be escaped; but the more difficult it is to reach absolute correctness, the greater need we have of some guide which shall reduce the unavoidable guess-work to its lowest terms, and to save us from manifold hazards which result from not only guessing at facts, but at the effects of those facts.

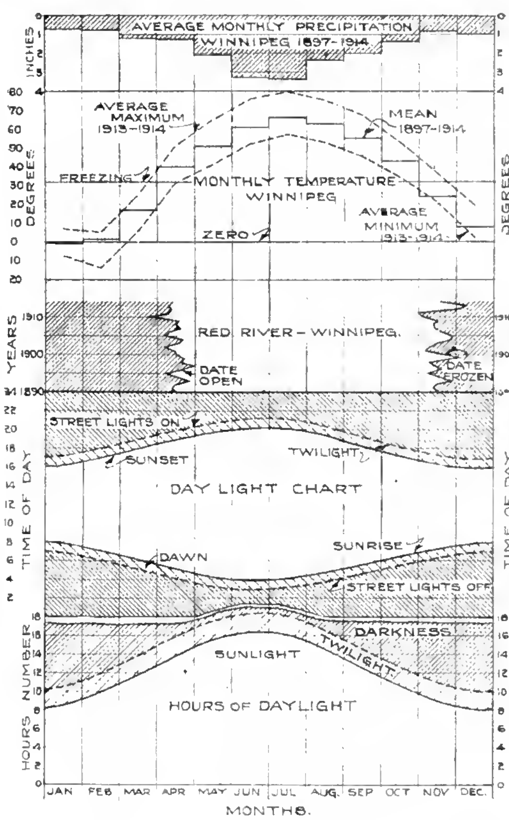
Whatever care we use we can never attempt with success to fix the exact point where economy ends and extravagance begins, but the graphic method helps us to establish certain narrow limits in either direction, somewhere within which lies the truth, and anywhere outside of which lies a certainty of error.

The final results must, of course, always be modified according to the results desired, conditions of working, the personal elements, etc., and accurate computations made for each particular case. The whole value of the charts shown this evening lies in their suggestive possibilities, as no attempt has been made to apply them to any specific case.

The continuation of this article, which will appear in a subsequent issue, covers the mathematical phase, starting from the simple geometric definition of a point in space moving in the shortest direction between two points generating a line, or one dimensional unit, movement of the line generating a plane or two dimensional unit, motion of the plane in a direction not contained within itself, generating a cube of three dimensions, and so on.

There will be explained more fully the two dimensional planes, containing the X and Y axis, which divides the plane into four quadrants, also positive and negative numbers, rectangular and polar co-ordinates, complex quantities involving the quadratic or square root of minus one quantities, which are so helpful in solving alternating current computations, and the equations for the straight line, circle, parabola, hyperbola and higher curves; graphical calculus; including integration and differentiation.

The graphical analysis of all of these gives a much clearer insight into their value, and allows the average individual to apply them daily to the solution of what would otherwise appear very complex problems. Until recent years



Daylight-temperature-precipitation chart for Winnipeg.

it was regarded as a very advanced and difficult branch of pure mathematics, its knowledge being the possession of a privileged few and especially endowed mathematicians.

The study of graphics is a common one, and no branch of mathematics knowledge has a more practical application. This is as it should be, for the fundamental ideas of graphics are common possessions.

New Books.

Kidder's Architects' and Builders' Pocket Book—a handbook for architects, structural engineers, builders, and draughtsmen, by the late Frank E. Kidder, C. E., Ph.D., Thomas Nolan, Editor-in-Chief; sixteenth edition; John Wiley & Sons, Inc., New York, publishers; price $5 net.

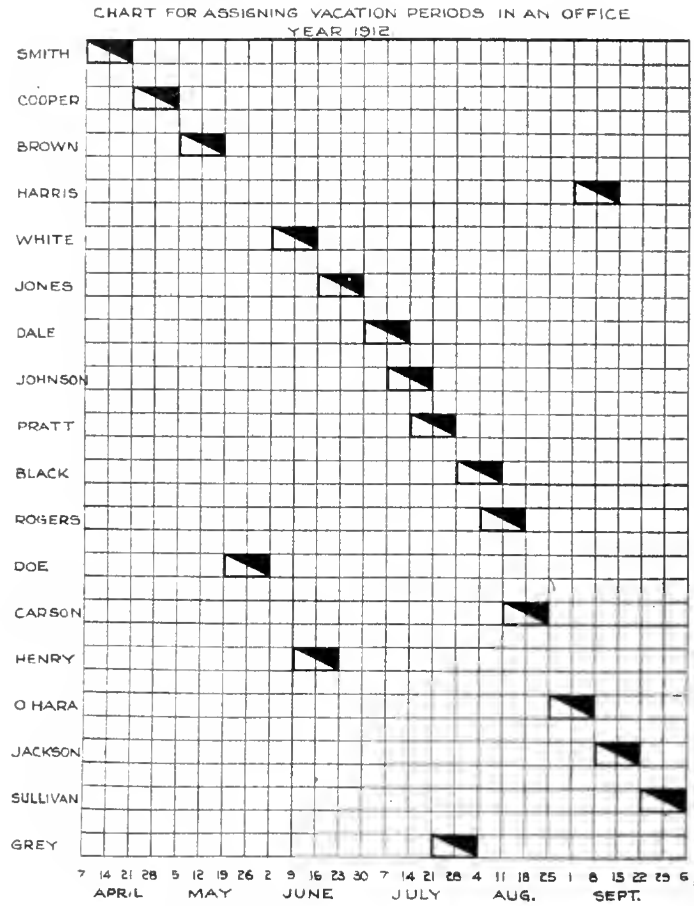


Chart for assigning vacation periods in an office.

The present edition is the result of an entire re-writing and resetting of the earlier editions. This book should prove particularly valuable as a reference, as its very broad scope may be gathered from the following brief review of the contents. Part I. deals with practical arithmetic, geometry, and trigonometry. Part II. deals with the strength of materials and the stability of structures, under the following chapter headings: (1) Explanation of terms used in architectural engineering; (2) Foundations; (3) Masonry walls, footings for light buildings, cements, and concretes; (4) Retaining-walls, and vault-walls; (5) Strength of brick, stone, mass-concrete, and masonry; (6) Forces and moments; (7) Stability of piers and buttresses; (8) The stability of masonry arches; (9) Reactions and bending moments for beams; (10) Properties of structural shapes, moment of inertia, moment of resistance, section-modulus, and radius of gyration; (11) Resistance to tension, properties of iron and steel; (12) Resistance to shear, riveted joints, pins and bolts; (13) Bearing-plates and bases for columns, beams and girders. Brackets on cast-iron columns; (14) Strength of columns, posts and struts; (15) Strength of beams and beam girders. Framing and connecting steel beams; (16) Strength of cast-iron lintels and wooden beams; (17) Strength of built-up, flitched and trussed wooden girders; (18) Stiffness of continuous girders; (20 Riveted steel plate and box girders; (21) Strength and stiffness of wooden floors; (22) Wooden mill and warehouse construction; (23) Fireproofing of buildings; (24) Reinforced-concrete construction; (25) Reinforced-concrete factory and mill construction; (26) Types of roof-trusses; (27) Stresses in roof-trusses; (28) Design and construction of roof-trusses; (29) Wind-bracing for tall buildings. Part II. contains useful information for architects, builders, and superintendents, under the following chapter headings: (1) Heating and ventilation, heat, fuel, gas and gas-piping; (3) Lighting and illumination of buildings; (4) Electric work for buildings; (5) Architectural acoustics; (6) Miscellaneous data. 1816 pages; flexible covers; well illustrated; 4½ by 7 ins.

Haddin & Miles, Limited

It is announced that the name of the John Galt Engineering Company, Limited, has been changed to Haddin & Miles, Limited. The company have offices in Winnipeg and Calgary, the Winnipeg address being the Curry Building. They will specialize in the design and construction of waterworks, sewerage, sewage purification works, electric lighting and general municipal engineering. Mr. John Haddin, M. Can. Soc. C. E., A. M. I. C. E., well known throughout the Dominion in connection with his work in the John Galt Engineering Company, Limited, is the chief member of the firm.

Sub-contractors on Rogers Pass Tunnel Win Suit for Bonus

Damages for breach of contract in connection with construction work on the Canadian Pacific Railway tunnel at Rogers Pass were recently awarded McIlwee & Sons, of Denver, Col., in their claim against Foley Bros., Welch & Stewart, of Vancouver, B. C., by a judgment of the Privy Council, delivered in London, England. The exact amount of damages has not yet been decided, but it is reported that the council upheld the principle that McIlwee & Sons were entitled to full damages, including profits, just as if they had been allowed to complete the contract.

After Foley Bros., Welch & Stewart secured the contract for boring the five-mile tunnel at Rogers Pass, they sublet the contract for the pioneer and center headings to McIlwee & Sons, offering as a special inducement for rapid work a bonus of $1,000 a foot for every foot over a stipulated advance to be made each month. McIlwee & Sons began work and made such rapid progress that at the end of three months they had a claim for bonus amounting to over $200,000. Difficulties then arose between the engineers on the work and McIlwee & Sons were ordered to stop work and vacate the contract for alleged refusal to obey the orders of Foley Brothers' engineers. After a period of six weeks permission was given to McIlwee & Sons to resume work, but instead they quit work entirely and brought suit for $500,000 for breach of contract. The amount was later increased to $800,000.

Bill to Include Outside Contractors Rejected

The Bill of the Montreal Council amending the by-laws contained a clause imposing a tax of $50 on contractors from outside municipalities doing work in Montreal. When the Bill came before the Private Bills Committee on February 11 it was very strongly opposed and was rejected. Alderman Turcot spoke in favor of the tax, pointing out that contractors from outlying districts could come into Montreal and get contracts while Montreal contractors had to pay a tax before seeking business in outside municipalities, and several complaints had been received of unfair treatment of Montreal contractors. The Hon. Walter Mitchell objected to the clause on the ground that it might deprive citizens of the advantages of competition and thus result in higher prices.

Is It Any Wonder It Sets?

Here is a new definition of that prosaic material, Portland cement, by Mr. Jerome Cochran, an American author of technical repute:—"Portland cement shall be defined as the finely pulverised product resulting from the calcination to incipient fusion, of an intimate mixture of properly proportioned argillaceous and calcareous materials, and to which no addition of other material greater than 3 per cent. has been made subsequently to calcination. No slag, pozzolana, sand, nor mixed cements will be accepted under this classification. In other words, the cement shall be manufactured of a mixture of argillaceous and calcareous material in definite proportions, and shall contain no furnace slag, grey limestone, hydraulic lime or trass."

Personals

Mr. P. A. Macdonald, the recent appointee as Manitoba Public Utilities Commissioner, who succeeds Mr. H. A. Robson, K.C., was born in Gananoque, Ont., in 1857, and educated at Queen's University, graduating in 1876. Following his graduation he studied law in Toronto and began practising in Winnipeg in 1880. In 1888 he was appointed Master and Referee in the Court of King's Bench, which position he held until 1911, when he resigned to open an office for private practice. The new Commissioner thus brings to his work qualifications and experience which eminently fit him for the position. His many years of service as Referee and Master in the Court of King's Bench brought him in touch with law and business of various kinds. His appointment

Commissioner Macdonald.

on numerous boards of arbitration—notably the labor dispute between the C. P. R. Company and its employees in 1908, of which board Mr. Macdonald was chairman—also shows a widely-recognized public appreciation of his sound judgment.

Commissioner Macdonald will be assisted in his work by an engineering staff, who will not only be at the service of the Commission in aiding investigations and settling technical disputes, but will also be available for the purpose of conferring with and advising upon the operation of telephone, gas, electric, and water supply systems, whether private or municipal, in any matters arising in the course of business. By the aid of these engineers the Commissioner will be relieved of the hearing of conferences between persons interested in purely technical matters, and will thus be relieved of certain burdens of office and left freer to devote his time to larger administrative work.

Mr. Seton Goes to Ottawa

Mr. Bertram W. Seton, a member of the Dominion Engineering and Inspection Company, has temporarily severed his active connection with that company to take charge of the Adjustment Department of the Imperial Munitions Board for such time as the Board will require his services. He commenced his duties on February 21, his headquarters being in Ottawa. Mr. Seton was born in Australia and obtained his early mechanical engineering experience at the Sydney Technical College in New South Wales. He also gained considerable practical experience in mechanical engineering shops in the same city. Later he spent some time at sea in the capacity of engineer on steamships plying between Australian ports, Japan and England. Following his sea experience he held an engineering position with William Beardmore & Sons' Naval Construction Works in Glasgow, Scotland, and afterwards was inspecting engineer with E. G. Carey, consulting engineer, Glasgow. Mr. Seton came to Canada in 1911 and organized the Dominion Engineering and Inspection Company jointly with Mr. H. J. Griswold, of Montreal, and for some time has had charge of the Toronto end of this firm's business. The position to which Mr. Seton has been appointed is a responsible one, and his wide technical and mechanical experience will prove invaluable in adjusting and overcoming any difficulties which may be met with in the manufacture of munitions.

Mr. Bertram W. Seton.

Obituary and Mainly Constructional

Precision Tool and Machinery Company, Limited, Montreal, have registered.

Gilletz & Company, builders and contractors, Montreal, Que., have registered.

Mr. Alphonse Venne, architect, has been re-elected Mayor of St. Lambert, P.Q.

The Kingfisher Mining and Development Company, Winnipeg, Limited, have been incorporated.

The Canadian Highway Engineering and Contracting Company, Montreal, Que., have registered.

Building permits to the value of $12,810 were issued in Toronto during the first eight days of February.

The contracting firm of James Worswich & Company, Limited, Winnipeg, Man., have increased their capital to $200,000.

Building operations in Quebec City are beginning to take an upward trend. During the week ending February 12 ten permits, of a value of $18,400, were issued.

The management and employees of the Canada Metal Company, Toronto, on February 12 laid the foundation of what will be one of the largest shot factories in Canada.

The death of Mr. F. W. Spencer architect, of Sydney, N. S., occurred on the 9th inst. Mr. Spencer, who was 47 years of age, had been engaged in his profession in Sydney for a number of years, and had designed a number of the larger buildings in that city.

Mr. Alexander C. Humphreys, president of the Stevens Institute of Technology at Hoboken, N. J., and one of the leading engineers of the United States, was the speaker at the Canadian Club luncheon held in the Chateau Laurier, Ottawa, on the 10th inst.

Mr. Walter R. Leavens passed away at his home in Hallowell Township, Ont., recently, at the age of 59. He had been road surveyor for the township of Hallowell for many years, and had superintended the construction of most of the bridges in that district.

Mr. H. S. Van Scoyoc, chief engineer, Toronto-Hamilton Highway, read a paper on Wednesday, February 16, before the American Concrete Institute at their Chicago Convention. The subject of Mr. Van Scoyoc's paper was, "Construction of the Toronto-Hamilton Highway by Day Labor."

The Board of Control of the city of Toronto have recommended the expenditure of $60,000 on equipping the new Registry Office building with steel filing apparatus and other metal furniture, as well as the provision of electric lighting fixtures. This equipment was not included in the building specification.

Mr. Henry Brown, manager of the South Stukely Marble Quarry, and formerly of Waterloo, Que., died recently. When a young man he entered the lumber business, and later on took up marine diving, inspecting steamers in Montreal harbor for some years. Subsequently he opened up the marble quarries at Philipsburg and South Stukely, Que.

Mr. W. G. Mackendrick, of the Warren Bituminous Paving Company, has been made a Captain in the British Army. Mr. Mackendrick went to England and offered his services to the Government in any capacity. He was granted the rank of Captain and sent to France in connection with roadway work, for which he is well qualified by experience and training.

It is doubtful if any corporation in Canada has supplied a larger number of recruits for military service in proportion to the size of its staff than has the Nova Scotia Steel and Coal Company, 721 of whose employees have volunteered for military service in various units. This number is equivalent to about forty per cent. of those in the employ of the company who are of military age.

Filion & Freres, Limitee, is the name of a company incorporated recently at Montreal "to undertake the construction of structures, buildings of all kinds, roads, streets, ways, canals, wharves, sewers, aqueduct systems, warehouses, and other works of a similar nature." Those interested are D., A., O., and J. Filion and A. Laverdure, all of Montreal. The capital stock of the company is $49,000.

The annual meeting of the Bricklayers' Union, Regina branch, was held on the 11th inst., and the following officers were elected for the ensuing year: president, G. Somerseiles; vice-president, J. Baggalay; financial secretary, George Alley; treasurer, J. Farmer. The membership of the Regina local has been well maintained, largely owing to the fact that a number of large buildings have been erected in the city during the season.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Aldborough Township, Ont.
The Township Council will shortly commence the construction of the Cahill, Mumford and Watson Drains. Clerk, E. A. Hugill, Rodney.

Brockville, Ont.
The Town Council will have plans prepared for the diversion of the Thames Street sewer. Engineer, G. H. Bryson.

Elma Township, Ont.
The Township Council intend to proceed with the construction and improvement of the Peet Drain. Clerk, George Lochead, Atwood.

Leamington, Ont.
The Town Clerk, R. M. Selkirk, will receive tenders until March 10th for the construction of approximately 16,000 square yards of concrete pavements. Plans at offices of the Clerk and the Engineer, J. J. Newman, C. E., Windsor.

London, Ont.
The City Council have decided to have plans prepared for asphalt pavement to be laid on Dundas Street E. Estimated cost, $30,000. Engineer, H. A. Brazier.

The City Council propose to lay an asphalt pavement on Beaconsfield Avenue and will shortly call for tenders on the supply of tile for sewer purposes. Engineer, H. A. Brazier.

Plans are to be prepared for the construction of an 8-inch sewer on Linwood Street for the City Council. Engineer, H. A. Brazier.

Moncton, N.B.
The Town Council contemplate laying a pavement on Main Street and propose to issue bonds for this purpose. Clerk, J. S. Mager.

Scarboro Township, Ont.
The Township Council will shortly commence the laying of watermains on Queen and Victoria Streets and Windsor Avenue. Engineer, F. Barber, 57 Adelaide Street E., Toronto. Estimated cost, $5,000.

Tillsonburg, Ont.
The Town Council are considering the laying of sewers to the buildings used by the soldiers, and the installation of shower baths. Particulars from Councillor Conn.

CONTRACTS AWARDED

Montreal, Que.
The contract for the installation of a pump at the Papineau Avenue Pumping Station has been let by the City Council to Canadian Allis-Chalmers Ltd., Rockfield, Que.

Sarnia, Ont.
The City Council have awarded a contract for the construction of vitrified sewers to P. Corrigan, 410 Brock Street.

Railroads, Bridges and Wharves

Calgary, Alta.
The City Council propose to call for tenders on the supply of 342 tons of steel required for the completion of the Centre Street Bridge. Clerk, J. M. Miller.

Detroit River.
The Department of Public Works, Ottawa, have provided in their estimates for channel improvements between Fighting Island and the Canadian Side, estimated to cost $57,000. Secretary, R. C. Desrochers.

Public Buildings, Churches and Schools

British Columbia Province
The Dominion Government Department of Public Works have provided in their estimates for the erection of the following buildings :— Merritt, Public Building, $25,000; Mission City, Public Building, $20,000; New Hazelton, Drill Hall, $9,000; Penticton, Public Building, $15,000; Powell River, Public Building, $20,000; Prince Rupert, Quarantine Station, $8,000, Public Building, $147,000; Revelstoke, Public Building, $50,000; Sidney, Public Building, $17,000; South Vancouver, Post Office, $60,000; Trail, Public Building, $20,000; Vancouver, Postal Station, $124,000, Drill Hall, $94,000, Detention Building, $55,000; William Head, Quarantine Station, $75,000.

Orangeville, Ont.
Dufferin County Council have authorized the County Clerk to call for tenders on re-wiring the Court House and Registry Office to comply with Standard Regulations. Clerk, J. C. Reid.

Orford Township, Ont.
Tenders on the erection of a school for the Trustees of School Section No. 7 will be received until March 10th by the Secretary, J. D. Anguiss, Muirkirk. Pressed brick construction. Estimated cost, $5,000.

Peace River, Alta.
The Presbyterian Congregation have purchased a site for a church and work will start in the spring. Pastor, Rev. W. Granan.

Peace River Crossing, Alta.
The Town Council are considering the erection of a Municipal Office and Fire Hall; but may not start work for two months. Secretary, L. W. Divine.

Stamford Township, Ont.
The Trustees of School Section No. 2 have decided to build a school and will call for tenders shortly. Plans are being prepared by J. Upper Collins, 49 Benson Street, Niagara Falls.

St. Marie, Que.

Department of Railways and Canals, Canada

Dartmouth Branch Line
BUILDINGS

Notice to Contractors

Sealed tenders addressed to the undersigned and marked "Tender for Buildings on the Darmouth Branch Line," will be received at this office until 12 o'clock noon on **Wednesday, March 15th, 1916.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, at the office of the Chief Engineer, Canadian Government Railways, Moncton, N.B., and at the office of the Engineer in Charge, Dartmouth, N.S.

An accepted bank cheque on a chartered bank of Canada for an amount equal to ten per cent. of the total sum tendered made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

J. W. PUGSLEY,
Secretary.
Department of Railways and Canals.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.- 92982. 8-9

Strauss Cantilever Swing Bridge

During the past fifteen or twenty years improvement in movable bridges has been confined largely to the very great advances in bascule design. More recently the vertical lift type has also undergone extensive development. The swing bridge or horizontal draw type, however, has received comparatively little attention. J. B. Strauss, consulting engineer, Chicago, whose last contributions to bridge engineering was the counterbalanced lever lift bridge, has now developed a swing bridge which lays claim to much originality.

This design, known as the Strauss cantilever swing bridge, departs radically from all existing types, while at the same time having no elements which are unknown and untried. Its characteristic features are: First, the use of direct driven trucks running upon ordinary railroad rails to effect rotation; and second, the construction of the central portion of the draw span as a cantilever projecting beyond the centre pier with the arms pin-connected at their ends so as to constitute simple spans from the ends of the cantilever to the abutments.

Miscellaneous

(Continued from page 44)

Tilbury, Ont.
The Union Natural Gas Company, Sarnia, propose to lay a ten-inch steel gas main between Tilbury and Sarnia. Work will start in the spring. Particulars from S. L. McKay, care of the company. Estimated cost, $30,000.

Toronto, Ont.
The Board of Control will receive tenders until March 14th on the supply of one single truck double end car and one single truck double end car body, with electrical equipment. Specifications at Room 12, City Hall.

The Board of Control will receive tenders until March 7th for the construction of a radial brick chimney at the Don Roadway Incinerating Plant. Plans and specifications at office of the Street Commissioner, G. B. Wilson.

Vancouver, B.C.
The Canadian Pacific Railway Company, Montreal, contemplate the installation of a fifty-ton electric crane at Burrard Inlet.

CONTRACTS AWARDED

Niagara Falls, Ont.
The City Council have let the following contracts for waterworks supplies:—brass work, Mueller Manufacturing Company, Sarnia; hydrants, Doherty Manufacturing Company, Sarnia; gate valves, James Morrison Brass Manufacturing Company, 93 Adelaide Street W., Toronto.

Committee Advocates Mortar Bed for Wood Blocks

A mortar bed for wood-block paving, instead of a sand cushion, is recommended by Clyde H. Teesdale, H. S. Loud and Frank Cherrington in their committee report submitted at the annual meeting in Chicago of the American Wood Preservers' Association. A 1:4 mixture, brought to a thickness of from ½ to 1 in. by templates, and containing just enough water to insure a proper setting of the cement, is advocated. The intention is to produce a granular mixture which may be raked to the desired grade.

Under certain conditions, especially where vibration may be expected, the committee report specifies that a mortar cushion may be omitted and a bituminous coating of one or two thicknesses, spread upon the smoothly finished and thoroughly dry concrete base, substituted therefor. A bituminous filler for the joints is recommended.

In another report to the same association Mr. Cherrington gave the results of a circular letter requesting information as to wood block paving practice in a number of cities. Of 155 cities circularized replies were received from seventy-nine. The majority called for a bituminous filler, with pitch having a slight advantage over asphalt. The fafored cushion is shown to be about equally divided between sand and mortar. The heavy creosote is by far the most popular preservative oil.

The data show that very few cities install the blocks by ramming the rows or courses tightly together. Most of the pavements are laid with the blocks in slight contact or by leaving interstices of at least one-eighth of an inch between the ends of the individual blocks. A large majority advocate laying the blocks at an angle of 90 degs. with the curb line.

Slipperiness of wood block pavement is retarded, up to six per cent. grades, with either lug blocks, creosoted lath strips or beveled blocks. Very few cities specify expansion joints transversely; most of them require a 1-in. joint parallel and adjacent to each curb. These expansion joints are filled with asphalt, pitch, fiber or sand, the preference being in the order named. In only two instances was a cement grout filler specified for wood blocks.

Excavation to Backfill in One Handling via the Roof

In the east portal of the Twin Peaks tunnel which the city of San Francisco is constructing as a municipal venture, a considerable length of the concreting was done in open cut. It was found that the last of the excavation in this section could be expedited and that at the same time the work of backfilling on completed parts of the concrete arch could be cheapened by cutting through the arch and delivering muck direct to the backfill with one handling, using an inclined railway through the finished roof.

Loaded dump cars were delivered by gravity to the foot of the incline on the right, were drawn up by an electrically-driven endless-chain belt, and after being dumped in fill were returned empty down the incline on the left. About 10,000 cu. yds. of material were handled over this incline improvised after the work was under way. In making the openings in the arch roof the reinforcing was left in place so that the sections could be readily restored to normal.

While mucking was in progress the electric motor ran continuously, cars being handled at about five-minute intervals. The link belt operated by this motor carried dogs which engaged steel brackets riveted to the running gear of the dump cars, so that the mechanism required no attention at either end of the incline. From the top a slight descending grade delivered the cars to the dump by gravity. On the return incline the link belt, which was not provided with power, was controlled by a hand-operated friction brake working on the shaft that carried the link belt sprocket at the head of the incline.

The most important problem that had to be solved in getting the scheme to work satisfactorily was the proper grades for the inclines. The grades first selected were too steep and a reconstruction of the track was required. As finally adopted the ascending grade was made 28 per cent. and the descending grade 40 per cent. The cars handled had a capacity of 1½ cubic yards.

The work is being done under the direction of M. M. O'Shaughnessy, city engineer. The escalator was designed and built by the contractors, R. C. Storrie & Company, of San Francisco.

Steam engine indicators for determining governor effort have been employed successfully in the River Mill plant of the Portland Railway, Light & Power Company. Company engineers working on this problem concluded that simultaneous pressure records, secured on each end of the governor cylinder, form the most satisfactory basis of rating, because under test the conditions are identical with those of normal operation, and elaborate changes of the mechanism are unnecessary. Graphic record pressure gauges were used, equipped so as to increase the speed of chart travel and produce a record with appreciable length in the space required for the governor to operate through a considerable part of its travel. Charts were taken from indicators on each end of the governor cylinder so as to secure a continuous record on the cards of the varying pressures from each side of the governing piston throughout two complete strokes or one cycle of operation.

Good Roads Enthusiasm

MONEY wisely invested in providing good roads is one of the best legacies the people of today can leave to posterity. Good roads are an economic necessity, essential to all the phases of our social and commercial intercourse and a prime factor in the development of the province. The highways we have always had with us and always will. Upon them we meet with a common feeling of ownership and it is our duty to ourselves to improve our economic conditions by paying greater attention to the prosecution of highway improvements.

Road improvement is a matter of deep interest throughout the farming districts of the Dominion. Every journey is wholly or in part over the common road, and the comfort and prosperity of the agricultural community and, therefore, of the cities and towns, are closely reflected in road conditions.

Steam and electric railways are all-important. Yet neither of these does away with the necessity for good highways. They rather increase the demand. Railways bring development, and development means more people on the land, and more production, with an attendant greater use of local roads. Observation appears to bear out the statement that good highways are more generally found adjacent to steam roads or suburban electric lines.

Appreciating the necessity of the situation, a number of Canadian Good Roads organizations have for some years been endeavoring to accelerate the movement towards better highways by every means in their power and from the number of associations formed throughout the Dominion of Canada, the keen interest taken, and the enthusiasm shown, by the members of the associations, it is evident that substantial progress is being made. This is further evidenced by the greatly increased mileage of good roads throughout the Dominion. In Ontario, interest in the good roads movement has been further stimulated by the passage of the Macdiarmid bill which now, we believe, justifies this province in claiming that the road laws of Ontario are the best in the Dominion.

* * *

That the Canadian people are becoming educated and are realizing the benefits of good roads has been amply evidenced by the co-operative spirit reported throughout the various conventions recently held at many points in the Dominion. Among these may be mentioned the Conference on Road Construction for county superintendents and engineers recently held by the Ontario Department of Highways at the Parliament Buildings, Toronto, to promote a closer relationship between the engineers of the department and the county superintendents, and effect a more efficient prosecution of highway improvements. The recent successful meeting of the Ontario Good Roads Association, a report of which is printed in this issue, also clearly demonstrated the great advances that are being made all over the province of Ontario. In Alberta, at a recent convention, Mr. Charles Steward, Minister of Public Works, mentioned the decision of that province to lay before the provincial authorities a proposal for the appointment of a highway or good roads commission, as the best solution of the complex and difficult problem of providing the province not only with efficient and serviceable roads, but also with an effective road maintenance system. And last, there is the work done by the Manitoba Good Roads

Association and the Manitoba Government which, under the efficient direction of Archibald McGillivray, Comissioner of Highways, have completed 266 miles of roads out of 373 miles under construction. The progress of the Good Roads Movement in Manitoba is described by Mr. McGillivray in an article reproduced elsewhere in this issue. The good work of the Quebec Department of Roadways, which, under a most energetic management, has done wonders in the past two or three years, is also outlined in this number.

* * *

The climax is reached, however, in the interest being taken in the Third Canadian International Good Roads Association Congress to be held in Montreal, March 6 to 11. The consensus of opinion is that this International Congress is providing a long-felt want, as all evidence shows that the information provided at the last two congresses has been of inestimable value to those interested in improving and developing the roads of the Dominion.

Summed up, Good Roads are an absolute necessity if the country is to continue progressive and the evidence is that public opinion is being thoroughly aroused to the advantages of good roads so that development may proceed along the broad lines that are essential to the continued progress and prosperity of the Dominion. The success of the Good Roads Movement, however, still depends on further educating the public to its many great advantages, until they became convinced that every dollar wisely and efficiently spent for this purpose is an investment that will pay an interest in gold dollars, to say nothing of the added pleasure in life, the added pride the individual will feel in his surroundings and the added comfort during the hours actually spent passing up and down the highway.

Good Roads in War Time

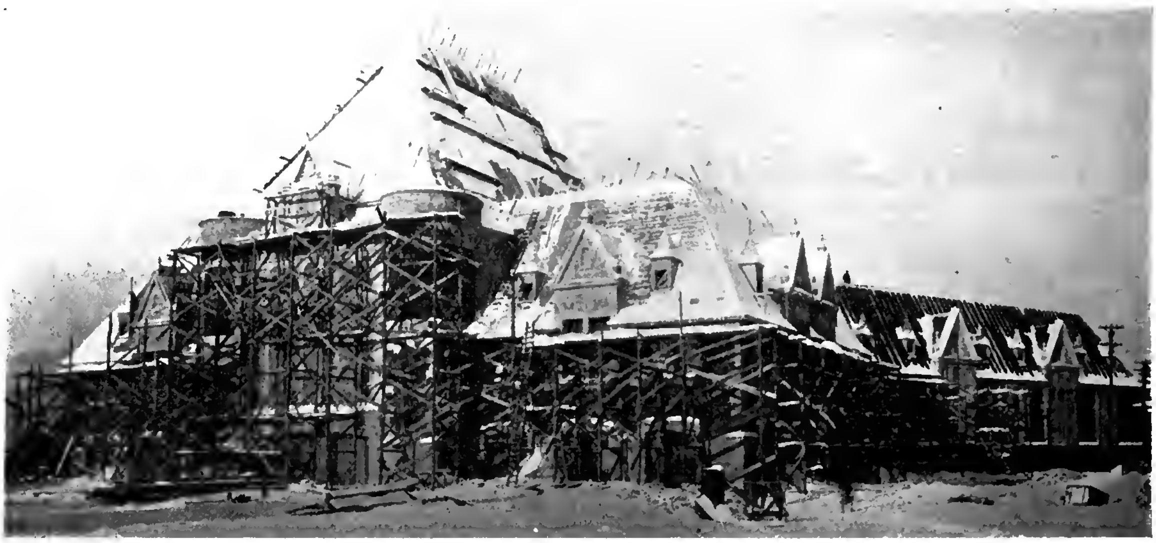
Canadians at this time should be specially interested in the address by Major Amos A. Fries, corps of Engineers, United States Army, on "The Value of Permanent Highways for National Defense," delivered at the Second National Conference on Concrete Road Building held in Chicago, February 15th, 16th, 17th and 18th, 1916. He urged the increased value of permanent roads under present methods of warfare where motor vehicles play such a prominent part. He declared that the use General Joffre made of motor cars and good roads around Paris in August 1914 saved the city and halted the German offensive. He spoke of the value to the United States of permanent roads along the coasts and land boundaries. Even when a considerable distance from the borders East and West roads would be of great value if North and South feeders were built as movements over them could be made without the knowledge of the enemy thus providing the surprise so essential to success.

Progress on Quebec Union Station

Considerable progress has been made in the construction of the Union Station, Quebec, by the contractors, W. S. Downing-Cook, of Montreal. The general plans of this building were shown in our issue of November 24, 1915. The exterior of the building is now practically completed; the power house is also completed, the boilers are in position, and the general building is under steam. The exterior is of Chateauvert stone, with Argenteuil granite. The window frames and iron doors are in place, and the exterior iron sashes ready for installation. The gypsum block covering is now on, and the roof has only to be sheathed and covered with copper.

In the interior the partitions are being made ready for the plastering; brick and facience work in the concourse has been started, and work will he commenced on the ticket lobby. The brick work here is of an unusually difficult character. Nearly all matters connected with the general office building have been settled, including the re-arrangement of the ticket office; an exception is the lighting fixtures, and this will shortly be under consideration.

In the spring the old station will be removed and broad sidewalks enclosing the plaza and road from St. Paul Street to the Henderson Street entrance, together with lamp standards, started on. The object is to complete portions of the station to enable the railway companies and the public to use them in June. Mr. H. E. Prindle, of Montreal, is the architect.



General view of construction work on Quebec Union Station.

Third Canadian and International Good Roads Congress, Montreal, March 6-11.

B. Michaud, President

Geo. A. McNamee, Secretary

Evidence of the keen interest being taken in the Third Canadian and International Good Roads Congress, which is to be held at Sohmer Park from March 6th to March 11th inclusive, is shown by the number of inquiries received daily by Secretary G. A. McNamee.

The congress will have eight business sessions, not including the official opening and at each of these certain aspects of the road question will be discussed by experts in that line. It is the opinion of these well-known men that the highway authorities wish to hear and profit by. The aim of the congress is not to be the means of advocating the construction of any one kind of road, but to disseminate information as to the value of good roads to all industries, and the best methods of constructing and maintaining them. There will be papers on the construction of roads, methods, maintenance, bridges, machinery, materials, how to successfully meet difficulties of various kinds, etc. The majority of the speakers will be practical men, who have had to solve problems either of construction or maintenance.

The Lieut.-Governor of Quebec has promised to open the Congress, and invitations have been forwarded to many prominent men associated with the good roads movement. The following are some of the speakers and their subjects: Messrs. Gabriel Henry, chief engineer, Province of Quebec, "Gravel and Stone Roads"; E. Farfard, chief of equipment department, Province of Quebec, "Handling and Care of Machinery"; Alex. Fraser, engineer, roads department, Province of Quebec, "Highway Culverts"; J. W. Levesque, M. L. A., "Road Laws"; A. F. Macallum, city engineer, Hamilton, Ont., "Creosoted Wood Block Pavements"; J. Duchastel, engineer, City of Outremont, P. Q., "Brick Highways and Streets"; W. Huber, engineer, Ontario Highways Department, "Maintenance Systems"; W. H. Connell, chief of the bureau of highways, Philadelphia, "Maintenance Materials and Methods"; Frank Smith, consulting engineer, New York, "Bituminous Macadam, hot mix, using asphaltic binder"; Prof. A. H. Blanchard, Columbia University, N. Y., "Bituminous Macadam, hot mix and penetration methods using tar binder"; Major W. W. Crosby, Baltimore, "Drainage and Foundations"; Elmer Thomson, Auto Club of America, "Motor Traffic, its trend and effect"; Col. W. A. Sawyer, chairman of the Massachusetts Highways Commission, "Different Types of Development used under various traffic conditions." The Hon. T. H. Johnson, Minister of Public Works, Manitoba, will deliver an address; Mr. P. C. Emmett, secretary of the Manitoba Motor League, "The Legislative Aspect of Road Construction"; Mr. A. W. Dean, chief engineer of the Massachusetts Highway Commission; Mr. L. E. Allen, consulting engineer, Belleville; Mr. Percy H. Wilson, consulting engineer, Philadelphia; and Mr. A. G. Batchelder of the American Automobile Association.

General Types of Improved Roads—Methods of Construction and Maintenance

By George Hogarth, Assoc. Mem. C. S. C. E.*

THE program of road work to be undertaken during the coming summer will shortly be given consideration by the different councils in charge of municipal expenditure, and a short discussion of the various types of roads which are customarily built appears timely.

There are many details to be considered before adopting any particular class of road in a certain locality, and the more prominent of these are the estimated cost of the road per mile, the local material available for construction purposes, the road-making machinery or equipment possessed by the council or the use of which can be obtained if a contract is let, and the necessary local labor to accomplish the result.

A road used only by a small number of residents does not warrant great expense, and the simpler construction methods are usually employed. Where a highway serves a larger population, a heavier traffic is to be anticipated, and a type of road structure capable of giving satisfaction under such loading is necessary. A suburban road leading away from a town or city may be subjected to a large traffic composed of all the various sorts of vehicles usually met with, and such traffic calls for stout road construction capable of withstanding all the influences tending to destroy it.

Experience with the development of the traffic on main roads between cities and towns has demonstrated that the most substantial pavement is required in order that the road may be easily travelled at all seasons of the year. It is quite evident that roads must be constructed to carry the traffic which naturally reaches them, and to build a light surface on a highway subjected to a heavy traffic is hardly to be considered as economy. In many cases it is not difficult to decide on the proper kind of road to build, but the selection of a road surface to be placed on the more important thoroughfares requires earnest consideration, and it is suggested that where there is doubt as between a light and a heavy type of construction, the stronger be adopted, since traffic is expected to increase on properly built highways.

The earth road is probably to-day the one type of construction with which everybody is well acquainted, and when such a road is given any reasonable attention it gives fair satisfaction with light traffic. Such a road is constructed at a low cost, and during the dry months of the year it can be put to good use. No other type of road is so seriously affected by bad drainage, and great attention should be given to the side ditches and tap drains, to see that all water flows rapidly away from the road allowance. Water lying in the side ditches is an indication that the foundation of the road is in a soggy condition and the entire surface will soon be cut up and made into a mire. To prevent such a condition developing, proper attention should from time to time be given to the various parts of the road. Ditches should be cleaned out and rendered effective, and the split-log drag frequently employed to round up and surface off the crown of the road. This maintenance of an earth road is of great importance and every encouragement should be given to those endeavoring to carry out improvement along such lines. The results of such labor amply repay those in charge, and the more efficient road surface presented is much appreciated by the taxpayer.

* Chief Engineer Ontario Dept. of Public Highways.

In some localities sand roads are of frequent occurrence, and two methods of producing a good road surface might be considered. The first would be to endeavor to keep the road low and close to the water level of the surrounding country. Should the damp condition be maintained all summer a desirable road is produced. Should a more permanent type of surface be desired, the sand may be mixed with clay and the crown shaped up. Thorough attention should then be given to the drainage of side ditches, and by keeping the road dry and shaping it up at proper times a satisfactory result will be obtained.

Clay roads demand proper drainage from the first day they are constructed, and their improvement can be furthered by the use of an application of coarse sharp sand and dragging with the split-log drag. Good judgment and thorough working is necessary in applying the sand; surplus of either sand or clay being undesirable. Where heavy frost is experienced during winter seasons a clay road may become very soft in the spring of the year. A partial remedy for such a condition is a well crowned surface and an adequate depth and efficiency of drains and side ditches. The construction of a sand-clay road is not completed when the first effort is expended and finished. Such a kind of road is the only one obtainable in many localities and perseverance in reconstructing and maintaining it is essential to final success. With intelligent work applied to rounding up the crown and providing outlet for all water to run away from the road, great improvement will soon be shown.

Value of Gravel Roads

The application of gravel to an existing road marks a long step in advance in highway improvement. Gravel is cheap in many sections of the country, and the character of the surface which it produces is second only to the more expensive stone roads. A gravel road is easily constructed, readily repaired, and when well built is capable of carrying fairly heavy traffic. There are many methods of constructing such a road, and the almost universal and undoubtedly the cheapest appears to be to dump the gravel in a ridge in the centre of the road and let the traffic beat it down and consolidate it. Many people prefer to drive in the ditch or along the fences of such a road, and in many cases probably considerable damage is done to the shoulders and ditches before all traffic will naturally again keep to the centre. A better method to follow is to round up the shoulders of the road and spread and compact the gravel when placed. This practice may cost a little more, but the results will usually warrant the slightly larger outlay, and the people will appreciate the convenience with which the new road can be travelled. Careful maintenance of a gravel road is real economy, since a better surface is continuously secured and more wear is obtained from the one coating of gravel. Drainage also requires attention to prevent soft spots appearing in the road, and a small amount of money intelligently spent along these lines will be amply repaid in greater service.

To-day the stone or macadam road, composed of a layer of varying sized stones with a top binder of screenings or gravel, is receiving more consideration than ever before. The earth and gravel roads being weak in supporting power have crushed down under heavy traffic and necessitated the use of a stronger and more durable foundation. In the construction of these roads it is customary to use the local rock nearest to the site of the work. Some localities are provided with splendid road building rock of a hard and tough nature, while in others a softer rock may be all that is available. The character of the material composing the road is very important and if a hard, tough rock, possessing good binding qualities be used, it is natural to expect a very superior surface; while with a softer rock a grading down in the value of the roadway is expected. In other lines of business a lowering in the price of a commodity has resulted in an increased volume of trade, and with a steadily increasing demand for the better classes of road building material, a reduction of unit price would appear to be the best advertisement the quarries could have.

Treating Macadam Roads

Where a stone or macadam road has become dusty and worn, one method of repair is to clean it off, and during warm dry weather apply a coat of tar or asphaltic oil to the surface; this has the effect of eliminating the dust and furnishes a binder which for some time will absorb the particles of dust worn from the stone in the road. Should the road be subjected to very heavy traffic, the wear may be considerable and a smooth surface may be a necessity, in which case a thin layer of new stone may be applied to the road and the tar or asphaltic oil poured on and compacted, thus creating a smooth bituminous surface which gives a good wearing road. The application of the bitumen and the new layer of stone may be made by mixing the two in a mixer and then applying and rolling onto the road in a coat of definite thickness.

The bituminous pavements are very popular at the present time, and satisfactory results with this type of construction are being obtained.

In busy highways carrying heavy traffic the concrete road furnishes at the present time a stout foundation and a good surface possessing many points of interest. Concrete is not a new material of construction, and many stretches of splendid roads of this type are in use. The accepted method of construction to-day is to build a concrete slab probably six inches thick at the sides and eight inches thick at the centre, and having a width of a double roadway, which is now usually eighteen feet. This slab may be of reinforced or plain concrete, depending on local conditions, and the steepest grade to which it is advisable to construct it is four per cent. The completed roadway furnishes a surface which is very even and pleasant to ride over, and is to-day one of the accepted types of paving applied to heavy traffic highways.

In conclusion there are to-day various types of roads such as earth, sand, clay, gravel, stone, bituminous and concrete, each of which requires adequate drainage, proper maintenance and intelligent repairs in a more or less degree. Drainage is a necessity in every case, except in one class of sand road, and with good side ditches almost any type of road furnishes a relatively satisfactory surface. The maintenance and repair of roads is now being encouraged in many ways since such work is essential to preserve and keep the surface in a satisfactory condition, and when such a system is in proper operation all roads which are given attention should be passable at all seasons of the year.

North Shore Marine Drive, West Vancouver

By W. H. Larson*

THE North Shore Marine Drive is the initial section of that long-projected extension of the Pacific Highway which will extend eventually from Vancouver to Alaska. The municipality of the district of West Vancouver was the first to take active steps to carry their ambitions to a fruition. Aided by the active co-operation, advice and financial assistance of the Premier of the Province, Sir Richard McBride, a good roads enthusiast, the municipality has recently completed a magnificent section of permanent pavement.

On the 11th of August Sir Richard had the pleasure of formally opening this first section of the road. In his address he expressed surprise at the easy grades, the heavy rock cuts, the permanent and beautiful concrete bridges, and finally said that it was his conviction that the North Shore Marine Drive had no superior, in quality of construction and beauty of scenery.

The Drive has been in the development stage for the last four years. In 1913 the Marine Drive by-law was passed by the ratepayers of West Vancouver to provide for the permanent improvement. The war caused a cessation of all plans for some time, but after the municipality had failed in their attempts to finance the work the Cotton Company, Limited, of Vancouver, took up the work and accepted the bond issue in payment. The contract consisted of clearing and grading from Station 0 to Station 67, a reinforced concrete bridge, and four miles of asphaltic concrete pavement. It was the original intention of the municipality to put in a macadam roadway, but the contractors were successful in showing the false economy of constructing a macadam road, with a life of possibly three years, to be paid for with forty-year bonds; the plans and specifications submitted by the contractor for the pavement proper called for permanent construction—that is, one and one-half inches wearing surface of asphaltic concrete on a four-inch hydraulic concrete base.

Concrete Base.—After a careful study a concrete base was selected as more economical than a macadam or a bituminous one. The type adopted consisted of a four-inch base with the edges turned up to form a monolithic curb. The mix was one cubic foot of cement to nine cubic feet of sand and gravel. The concrete was mixed in an eighteen-cubic-foot Foote Mixer and hauled in Briggs concrete carts to extreme hauls of fifteen hundred feet. The concrete crew was organized as follows: four men at the mixer, seven men spreading, four single-horse carts hauling, two men on water supply pipe-lines, two men setting screens, and six men grading. This crew averaged one thousand square yards a day, and had a maximum of fifteen hundred. As the mix was low in cement and the base thin, extraordinary care was taken in workmanship and in the mechanical grading of the aggregate. Daily

½-inch	0.0
¼-inch	0.0

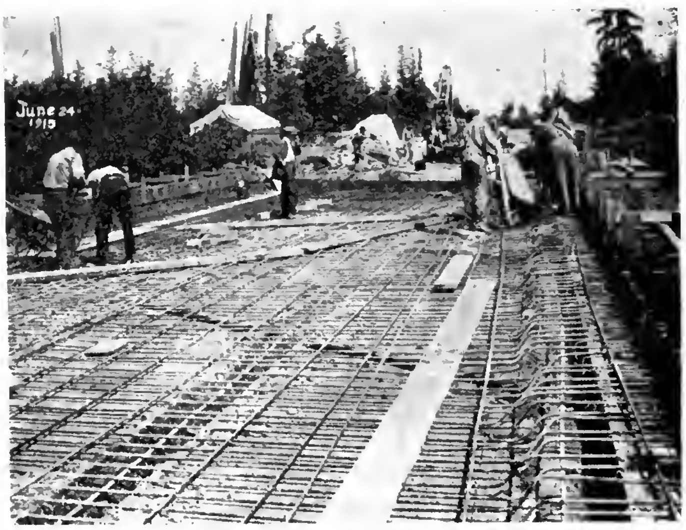
Two kinds of sand were at first used, the mix being one part of pumped sea sand, two parts of washed bank sand, and six parts of gravel. As a result of the above tests the pumped sand was discarded.

Asphaltic concrete wearing surface was mixed in a new type of portable plant built on the concrete mixer type, with a surrounding heat jacket with fire grates beneath. The plants are most economically worked in pairs, one gang handling both. The gang is organized as follows: 1 foreman, 1 steam engineer, 1 torch tender, 1 platform man, 1 dump man and fire tender, 1 wheelbarrow man for coarse fines, 1 wheelbarrow man for graded fines, 1 wheelbarrow man for sand, 1 asphalt kettle tender, 1 asphalt carrier, 1 water and chore team.

The street gang is organized as follows: 1 foreman, 1 roller man, 1 raker, 2 shovellers, 1 flush coat and squeegee man, 1 concrete sweeper, 1 asphalt tamper, 1 tender for asphalt kettles and fire wagons.

The sequence of operations is as follows: wheelbarrow men load the mixer with four cubic feet of coarse fines, four cubic feet of graded fines, and two cubic feet of asphalt sand. The torch man now inserts the kerosene torch into the mixer and the mineral aggregate is heated by the combined action of the torch and the heat from the fire beneath the drum. In about eight minutes the aggregate is thoroughly dried and heated to a temperature of about 250 to 275 degs. Fahr. The torch is now removed and the platform man puts 90 lbs. of asphaltic cement at a temperature of about 275 to 300 degs. Fahr. The asphaltic cement is passed to him in buckets by the kettle tender. The batch is now heated without the use of the torch, so that the bitumen is not exposed to the direct action of a flame at any time. The mixing action of the machine is that of kneading or folding. This action is superior to that of the pug-mill or paddle mixer for the mixing of asphaltic concrete, as the paddles have a tendency to separate the larger rock from the sand. This same point is noticeable in over-raked asphalt on the street; the rakes bring the larger particles to the surface. The dump man now dumps the batch into the Briggs concrete cart and the recharging begins. The cart is now moved over to the second mixer, which has followed up the same sequence of operations, but with all operations two minutes later. The cart is filled with the second batch and hauled to the spreading gang. The economic limit of haul with the single-horse carts we found to be

Ten ton roller on surface work, Marine Highway, B. C.



Reinforcement for river bridge, Marine Highway, B. C.

TABLE I—GRADING OF MATERIALS USED IN ASPHALTIC CONCRETE TOP

Sieve:—	No. 200	No. 100	No. 80	No. 50	No. 40	No. 30	No. 20	No. 10	¼-in.	½-in.

about two thousand feet; at this distance six carts are required; at a thousand-foot haul two carts will keep the plants working to full capacity. The material is now spread with shovels and raked to a true surface and thoroughly consolidated by means of a ten-ton roller. While the surface is still warm a seal cast of asphaltic cement is spread and then covered with a light layer of one-quarter-inch screenings which are thoroughly rolled in. The elements of prime cost of one thousand square yards of asphaltic wearing surface one and one-half inches thick is as follows:

At the plant: labor, 229 hours; asphalt, 21,172 lbs.; asphalt sand, 19.5 cu. yds.; rock fines, 58.5 cu. yds.; coal, 3.4 tons; kerosene, 48 gallons; water team, 11 hours.

Hauling hot stuff: single horse 32 hours.

Street gang: spreading labor, 139 hours; sweeping concrete, 31 hours; roller coal, 6.6 sacks; asphalt for flush coat, 3.9 bbls.; rock fines for squeegee, 2.5 cu. yds.

The method of obtaining the best grading of the mineral aggregate for use in this type of asphalt plant is somewhat different to that in use in larger and more expensive plants. The scheme used is that of blending two or more materials in varied proportions to obtain the required amount on each screen. The procedure is illustrated in Table I.

First, the various materials available are screened and their respective gradings placed in the table.

The ideal and the various materials are now studied with a view of selecting unit cubic feet or half cubic feet to a total number of ten, which is the box or batch size in use; which when combined will conform to the predetermined standard. The calculations are simple, and a few trials will at once show up the inherent possibilities of the materials. The success of this method depends upon the materials running uniform from day to day, and also upon the wheelbarrow men getting the right amount in each load. As to the first objection, the materials used were very good, and daily tests showed practically no variation. The second objection is more serious, and called for careful coaching of the laborer and frequent admonitions from the foreman. However, an error of one-half cubic foot is about the limit, and a study of the tabulation will show that this would cause no serious injury to the mix.

Daily samples were taken and analyses were made by competent chemists, who reported to the plant foreman. The plant foreman varied his mix as indicated by the daily tests. Tests as follows:—

Analysis of Asphaltic Cement

	High	Low	Average
Penetration 77 F. 5s. No. 2N. 100G	64	43	57
	%	%	%
Loss at 325 F. 20G for 7 hours ...	1.21	0.55	0.87
Soluble in carbon bisulphide (25C 18 hours)	99.71	99.51	99.63
Soluble in carbon tetrochloride (25C 18 hours)	99.57	99.40	99.46
Soluble in 86 Naptha (25C 18 hrs.)	78.12	75.36	76.80
Fixed carbon	10.80	9.15	10.17
Per cent. of asphalt in asphaltic concrete	10.20	7.20	8.03

Reinforced Concrete Bridge

The east branch of the Capilano River was spanned by two thirty-foot girder skew spans, with filled abutments and retaining walls. The girder type was selected in preference to an arch, as the character of the stream and the footings rendered the cost of the arch abutments prohibitive in price, and the necessary rise of the arch could not be obtained without unduly raising the grade of the roadway. The design consisted of main girders spaced six feet centre, connected by a transverse stiffening girder and a con-

Reinforced Concrete Bridge, Marine Highway, B. C.

crete deck slab. The spans were designed to carry a twenty-ton road roller, which gives an equivalent loading of 1,300 lbs. dead load and 1,100 lbs. live load per lineal foot or maximum moment of 255,000 foot-pounds. The unit costs of construction are as follows:—

Excavation for footings, per cubic yard		$0.88
Fill in approaches, per cubic yard		0.39
Reinforced Concrete:		
Screening gravel and teaming, per cu. yd. of concrete		$0.75
Labor, mixing and placing	do	1.81
Reinforcing steel	do	2.30
Reinforcing steel, teaming	do	0.10
Reinforcing steel, placing	do	0.62

Total	do	11.86
Concrete railing, per lineal foot		1.58

Maintaining the Public Highways

By R. H. Fair*

IN Canada at the present time we have one job to attend to. Those who are fit should don the khaki, and those who are not fit should assist financially and in every other way possible to bring the great world struggle to a successful conclusion. In doing so, it is not necessary to lose interest or sight of the great problems which present themselves in a young and growing country like Canada.

One of the problems I will mention in our home province and which, before the war broke out, was of the greatest moment—it is the question of building and maintaining the highways of Ontario. This will have to be grappled with because it affects either directly or indirectly every person in the province.

Great movements, to be successful, must be backed up by the majority of the people. Many great reforms have met disaster or have been retarded by trying to force them in advance of the sentiments of the people. Consider the great revolution which is to take place in changing the building and care of highways from the old form of statute labor—favored by some because of getting rid of the annual road tax, and, by others, because of the pride they have taken in their beats, although the latter are sadly in the minority—to a system of government and county control. When you think of it, the road that ten years ago was considered satisfactory is not considered at all an economical kind of road to construct for the mixed traffic of today. This means larger expenditures, which, outside of government or other assistance, must be met by a direct taxation, which should make it as light as possible on the rural population, so that the movement of people from urban to rural points, or vice versa, should not be hindered.

Education must go in advance of the Good Roads movement. The ratepayers should know, if possible, what type of road would be required in their municipality, what it would cost per mile and the share that each would be called upon to pay.

There have been many changes brought about by legislation and Good Roads Acts since such laws were first placed on the Statute books. For instance, this year, the percentage for construction has been raised from 33 to 40 per cent. and for the first time 20 per cent of maintenance requirements is to be paid by the government. However, I think that when things become normal again, there will be room for further improvement in the percentage of construction. I would suggest that the fees from auto vehicles be placed in a special fund for maintenance only and used for no other purpose. Then this percentage could be raised from year to year, as the fund would permit.

The argument is often raised by the farmers: "What's the use of building a first class road for the autos to destroy?" This could be offset if it was proved that the autos were paying their fair share for the use of the road.

There are a number of counties that are past the initial stages in the Good Roads movement. It largely depends upon their success or failure whether other counties, that have not taken up the work, do so or not. Before they go into the system of Good Roads, they are likely to make enquiries from counties that have tried it.

To sum up, the success or failure depends largely on the county roads engineer or superintendent, who is in daily touch with the ratepayers of the county. He should seize every opportunity to demonstrate the advantages of good roads and to publish in pamphlet form every detail for the expenditure of each piece of work, so that if anyone chooses he may know how the money has been spent on the piece of road opposite his own property. If you can convince them that there is no graft, that the money is being judiciously spent and that they are not being taxed unjustly, we shall soon have little or no opposition.

*Road Superintendent, Frontenac County

The Boston Elevated Railway Company, owners of a brick office building occupied by the Bay State Street Railway Company as headquarters of its electric freight business, recently moved the building about 150 feet to a new location, on Atlantic Avenue, Boston. During the process of moving, heating for the offices, which continued to be occupied without interruption, was provided by means of about 50 electric radiators, which were connected to the Elevated Company's circuits by means of temporary wiring. As the moving took place during mid-winter, the need of artificial heat presented a problem which could only be successfully met by the electric heating installation.

Quebec Province Added Three Hundred Miles Macadam Roads in 1915

THE progress of the Good Roads movement in the province of Quebec is well evidenced by the fact that during 1915 there was constructed in that province under the direction and with the aid of the local Government 295.6 miles of macadam roads and 140.7 miles of gravel roads, in addition to a very large amount of maintenance work, particularly on earth roads. The Department is well organized. The work of the instructors, contractors, and inspectors is clearly outlined and vigorously prosecuted.

A report just to hand of the Minister of Roadways, Mr. B. Michaud, indicates that the sentiment in favor of good roads has undergone a marked change throughout the province within the last few years. Instead of it being necessary for the Government to carry on a campaign of education, the people have actually taken the matter in their own hands, and are urging the Government to the limit to spend all the funds that are available on the amelioration of the roads of the province. The work is being carried out, as already noted, in a most scientific and efficient manner. A testing laboratory, referred to below, operates continually in the interests of Good Roads problems.

Gravel Roads

The Minister of Roadways expresses his opinion that while he is willing to admit the necessity of the gradual substitution of hard surface roadways, he believes that the gravel road is capable of rendering very distinct service. When it is properly made it affords as favorable a roadway for automobile traffic as for ordinary vehicular traffic, and it may well be employed in place of macadam, especially on account of its relative low cost—one-third to a quarter that of macadam. Regarding the use of gravel there are, however, two principal points to consider—the distance it has to be transported, and the quality of the gravel. Up to two miles the carrying of gravel is economical, especially if it is of a superior quality. Certain gravels have a binding quality, requiring neither rolling nor watering, and so their use saves a very considerable expenditure. Much depends on the quality of the gravel and on its cleanliness. A gravel containing more than twenty per cent. of earth matter should be rejected, or the earth separated out.

Macadam Roadways

Regarding macadam roadways, the province is divided into districts for purposes of construction and inspection. The supervision of this work is important and costly, but is one of the features that the Roadways Department considers most necessary. They work towards greater efficiency in this direction from day to day, and endeavor to keep their inspectors at maximum efficiency. This system of inspection is indicated in the following instructions, which are given out to the different inspectors:

Inspectors' Instructions

Teach the instructors the best method of making the macadam, draining, building the culverts, proper manner of disposing of the men over the work, and the necessary care of the machines. The inspector must assure himself that the workmanship conforms with the specifications furnished the instructor.

Re-set the machines in better position if necessary. Make little adjustments, which ought to be made without having recourse to repairers; have the mechanics make these little repairs.

Inspect carefully the works at least two days to each plant. If it seems wise to remain longer, advise the Department by telephone or send telegram to obtain authority.

Work seriously towards reforming the organization, so as to carry on the work economically; it is one of your most important duties. Dismiss immediately the useless or incompetent workman.

See that each course of stone is separately rolled.

See to it that the stone-dust is distributed over the road with a shovel, and be sure that this dust is not used to fill in depressions or left in heaps. See to it that the roller does not roll more than sixty feet in length at one time.

It is the duty of the instructor-inspector to study the instructions and duties of the instructor, of the man who operates the roller, and the man who operates the engine, that he may be well advised of the various operations and the better able to make his report. Every week it is his duty to fill in the blank report furnished and send it to the Department every Saturday evening.

In each municipality where an inspection is made inspectors are expected to get in touch with the superintendent or overseer of the work appointed by that municipality, as well as the Government instructor, where there is one.

In municipalities which have their own equipment, if the instructors or the superintendents are incompetent or fail to do their duty, advise the Department immediately by telegram and give explanations at length by letter. It is the duty of inspectors. The greatest care is enjoined on the inspectors as to the method of making their inspections, and very complete written instructions are provided.

Montreal-Quebec Route, Macadam made in 1915.

Provincial Roads

Montreal-Quebec Section.—This great highway, already the admiration of tourists, and which also has a very great value for the agricultural interests which it serves, is almost completed. The eastern division has a length of 48.37 miles. On the centre division 26.4 miles are finished and 6.63 miles well under way. On the west division 27.94 miles are completed, and the foundations laid on the remaining 20.5 miles.

Levis-Jackson Section. This is a stretch of roadway 90.15 miles long between Levis and the frontier. Unusual difficulties have been met with over this piece of roadway, but a total of 66.28 miles is complete.

Sherbrooke-Derby Line.—This is about thirty-two miles in length, from Sherbrooke to the frontier. 6.6

miles have been macadamized, 23.24 miles have been gravelled, and a short distance in the village of Rock Island has been gravelled and covered with tarvia. This is a most attractive road, following the shore of the beautiful Lake Massawippi, and constitutes, both for the agriculturists of this section and for the tourists from the United States, an improvement already full of advantages and promise. Many difficulties were met with on this work, but the contractors worked with a will, so that in one single season another artery of the Good Roads system of the province has been completed.

Chambly Road.—This is about twenty miles long, and is completed. It was constructed by the municipalities interested, and opens direct communication between Montreal and the frontier by way of St. Jean.

Some of the fine roadways of the province of Quebec are shown herewith.

The Testing Laboratory

The following interesting report by Gabriel Henry, chief engineer of the Department of Roads for the province of Quebec, indicates the care taken by this Department in the efficiency of the work carried on. It is headed "A Report concerning the examination, tests, and analyses of materials made at the laboratory of the Minister of Roadways of the Province of Quebec."

Materials generally sent to this laboratory consist of stones, gravels, sands, cements, and concrete pipe, which are examined from the viewpoint of their acceptability for roadway construction or for concrete work.

Stone.—Samples of stone are sent either by the instructors and roadways inspectors, by the municipalities, or by the owners of quarries who may propose selling stone to the municipalities. The choice of a sample of stone is an operation that requires considerable precautions. The quality of stones in one quarry may vary greatly from the stones in another quite close. Even in the same quarry one often finds stones of quite different qualities. In any quarry stones on

Banlieue to Three Rivers—Concrete laid in 1915.

the surface are not representative in general of those found at greater depth. In the same quarry we find different layers at different levels with stones of different natures.

Of course, the laboratory can only pronounce on the samples which are sent to it, and it frequently happens that these do not represent accurately the stones which it is intended shall be used. For example, a municipality, or an individual, sends a sample of stone taken from the surface of the quarry or from a layer of inferior quality. The report is unfavorable. Some time afterwards the same individual may send another sample taken from the same quarry but more carefully chosen, and the report may be favorable. It is neces-

Good Roads in Compton, P.Q., Macadam built in 1915, Road before, during and after construction.

sary that the attention of instructors, inspectors, municipalities, and quarry owners should be drawn to this matter.

Again, a stone of fair quality may easily be accepted in one case and refused in another. For example, one might accept a stone which is not very hard, though quite sound, for a road where the traffic is light or where automobiles do not pass, if the municipality is not able to procure better quality or may not be in a position to pay the necessary price; while for a road with more traffic it would be more economical for the municipality to procure a better quality. In this latter case the sample submitted would be refused. Sandstone may be accepted when the substructure of the road is very solid, but refused in other cases because it would be absolutely impossible to bind, employing a calcium binding. It will thus be seen that a multitude of considerations regulate the choice and acceptance of stone. In the laboratory the stones are examined from the viewpoint of their geological production, their nature, their hardness, their resistance to crushing and wear, their friability, and the facility with which they will bind themselves together.

Gravels and Sands

For the selection of samples of gravel the same remarks hold good as in the case of stone. Gravels and sands are examined either from the viewpoint of their employment in road construction or their use in concrete work. In the first case the examination consists in making note of the nature of the flints and grains which compose them, of their hardness, their size, and of the nature and proportion of the sand and earth matter present. This examination permits of issuing directions on the method of employing these gravels and making a choice between several gravels taken from different beds.

When the sands or gravels are to be employed in concrete construction work, one examines their nature, then establishes their granulometric form by means of sifting. The sifting determines the relative proportions of grains of different size. The granulometric degree of a gravel or sand is extremely important. A gravel or sand of which the relative proportions of different sizes are just right gives a cement more resisting than another in which the proportions are wrong. The granulometric study of sands and gravels before their employment in concrete means economizing cement in large measure, as well as obtaining a higher resistance.

The gravels to be used in the making of concrete are also examined for clay, organic matter, and earth matter which may be contained. Organic matters, even in very small quantities, prevent the hardening of the concrete. Plaques and briquettes of cement are made with the gravels and sands, and are tested with a tension machine, which indicates their resistance to compression in pounds per square inch. Certain tests are made after allowing the plaques and briquettes to stand in water for varying periods. If the resistance, either to compression or separation, is too low, these sands and gravels ought to be rejected.

Cements

Samples examined cover generally cements employed by contractors or municipalities in the construction of bridges and culverts or in the fabrication of various concrete pipe. The cement tests are made according to the method recommended by the Canadian Society of Civil Engineers, and show the density, the fineness, purity, the hardness in the early and in final stages, the constancy of volume, and the resistance of briquettes and plaqùes to compression and separation. Just as with sand, these two last tests are made with samples seven days and twenty-eight days old. These samples are made with tested cement and with sand known as the "Standard Ottawa Sand." This is a white sand which comes from Ottawa, Ill., and is now employed in such tests by all laboratories.

Concrete Tiles

Manufacturers of concrete tiles for the most part make their own pressure tests. The resistance to compression ought to be that of a good concrete—that is to say, at least 200 pounds per square inch at the end of one month. The concrete in these pipes is also examined as to its constitution.

A register of all the tests is kept in the laboratory. The samples submitted are also preserved.

The Good Roads Problem in Manitoba

By Archibald McGillivray*

DESPITE the fact that the year 1915 may be considered an off year in the expenditure of large sums of money in public enterprises, with the exception perhaps of those directly associated with a vigorous prosecution of the war, municipalities in the province were able to carry out such contracts as they were engaged in and others have contracted for fairly large expenditures.

The Municipality of Assiniboia completed its contract with the National Paving Company, of Winnipeg, for the construction of 5.42 miles of asphaltic concrete pavement on the Portage Highway. The total expenditure in connection with this contract was $163,000. This gives the above municipality 5.38 miles of continuous pavement 24 feet wide from the western limits of the city of Winnipeg and 4.00 miles of the 16 ft. pavement continuing from the end thereof, or a paved road from the city of Winnipeg to the village of Headingly, 9.38 miles distant to the west. The total cost of this mileage of road was $386,192.62, of which $85,733.50 was borne by the provincial government.

The municipality of St. Vital entered into contracts with the Guilbault Construction Company, of St. Boniface, for the construction of 0.8 miles of reinforced concrete pavement 16 feet wide, at the contract price of $14,120; and with Thos. Jackson & Sons, of the city of Winnipeg, for 5.4 miles of concrete pavement for the sum of $94,594. This work is on St. Marys Highway, leading from the city of St. Boniface to the south, along the east bank of the Red River. The first mentioned contract in the municipality was completed last year, and a start made by the Thos. Jackson & Sons on the grading of the second portion of the road, which portion it is proposed to complete early in the present year.

In the municipality of Wallace, situated in the extreme west of the province, the prosecution of its scheme to construct 194 miles of roads at the estimated cost of $301,500 was continued last year. A contract for the grading of an additional 58.0 miles to that previously under way was let to A. R. Boivin, of Winnipeg, last June, at the price of 20 cents per cubic yard, pit measurement. Contracts were also let for the construction of 9 reinforced concrete bridges and 3 reinforced concrete culverts, all of which bridges were constructed last year. It is the intention to gravel 105 miles of the roads included in the whole scheme and to bridge the total mileage with permanent structures.

The Municipal Council has just completed the sale of $40,000 worth of 40-year debentures to carry out its share of next season's programme of construction. The Provincial Government contributes fifty per cent. of the total cost of constructing gravel roads and permanent culverts and bridges, and 33 1/3 per cent. of the cost of graded roads.

The cost per mile for grading an 18-ft. roadway in this municipality averages about $800, constructing and placing pipe culverts about $110 per mile of road,

* Highway Commissioner for the Province.

and the average cost of gravelling with 525 cubic yards of gravel per mile is about $425.

Upon the completion of this scheme in hand this municipality will have what may be considered its leading market roads in splendid shape, and will have the foundation of a good system of main roads. The Municipal Council has authorization from the ratepayers to issue $150,000 worth of debentures bearing interest at 4½ per cent. per annum, $25,000 of which are for thirty years and the balance for forty years. Of this amount the proceeds $85,000 worth are as yet unexpended, and $45,000 yet unsold.

The assessed valuation of the taxable area of the municipality is $3,723,180, there being in all twelve townships in the municipality.

Four other municipalities were also engaged last year in constructing roads under the Good Roads Act, but these operated on a much smaller scale than the last mentioned municipality, although a well defined plan has been laid out in each of the municipalities. In the majority of municipalities in this province there is an averseness as yet to the issuing of long termed debentures for road construction purposes. The ratepayers appear more satisfied to proceed on the "pay as you go" plan. Whatever be the arguments in favor of following such a course, it will certainly require a number of years before the municipalities will have the systems of well constructed roads that many of them should have.

It is the aim of the Good Roads Department of the Government to induce the Municipal Councils to avail themselves of the assistance, both financial and engineering, provided in the good Roads Act, 1914, in their expenditure of this amount. The acceptance by the municipalities of this assistance and the direction of the annual expenditure made by them, if devoted along up-to-date and systematic methods, such as are laid down in the Act, would result in decided improvements in the conditions of the rural roads in this province. From the applications now being received from different parts of the province, it is obvious that the municipalities will more generally avail themselves of the assistance of the Act, and it is expected that the benefits resulting therefrom will induce many of them to undertake larger and more comprehensive schemes.

The intent of the Good Roads Act of this province is to formulate and assist municipal councils in building the main market roads in their respective municipalities, the construction of great provincial highways across the province being as yet considered of secondary importance to the establishment of local main road systems,—the extension and development of which would, of course, ultimately result in a provincial-wide system. The needs of the municipalities in providing the producer with better facilities in reaching his market are more apparent than the necessity of trans-provincial or even inter-urban communication, as there is no doubt but the improvement of market roads will assist materially in developing improved conditions between towns and villages.

The Act also provides for financial assistance to municipalities of fifty per cent. of the cost of the construction of permanent bridges and culverts. In many municipalities where such structures in considerable numbers are required, attention is being given to this phase of the road problem first. There is no doubt much wisdom in pursuing such a course, as a road cannot be considered any better than its poorest portion, and the existence of an improperly constructed bridge in a road is more to be avoided than an indifferently built roadway.

The Haldimand County Road System

By D. W. Burney*

IN this county we have 123 miles of road under our system, 25 miles of which has been graded and metalled and the balance are clay roads. This present season we expect to see them all graded for the first time. Four years ago we organized a maintenance system, dividing our 123 miles of road into forty divisions. The Superintendent, assisted by the Reeves of the different municipalities, made a selection of the best available men to act as foremen on the forty divisions. This system has given us good results.

In March we hold a conference for one day with forenoon and afternoon sessions. This conference is composed of the forty Foremen, the seventeen Councillors, the Engineer and Superintendent. The Superintendent presides and gives the opening address, we then have about six good practical lectures delivered on the different kinds of maintenance work. A limited amount of time is given after each lecture for discussion.

Each foreman is furnished with two time books, in which he keeps a record of the time of each person he employs and how employed. At the end of each month he forwards one of his time books to the Superintendent, who checks it over and then transfers it to a time sheet and certifies to its correctness. It is then forwarded to the Warden, who signs it and forwards it to the Treasurer, who issues a cheque to each person on the time sheet and forwards them to the foreman of the Division. The Superintendent in the meantime returns the time book to the foreman, who compares the cheques with his time book and then gives each person their cheque, having them receipt for same in a column in the time book for that purpose. The Superintendent keeps in his office a maintenance ledger in which is opened an account with each of the forty divisions, with headings as follows:—Grading, Leveling, Draining, Weeds, Repairs to Entrance Culverts, Road Culverts and Bridges, and Resurfacing and Repairing Metalled Roads.

As early as possible in the spring the Superintendent goes over each division with the foreman and decides what work is to be done the coming season, making an estimate of same. He submits his report to the Road Committee, who check it over, making what revisions they may think necessary, and hand it on to the whole council for adoption.

We usually spend about $6,000 on the whole system, averaging $150 to each division. This expenditure keeps our roads in good shape and our foremen take a keen interest looking after their division. After four years of experience in this system the people generally are well pleased with the results.

* County Road Superintendent, Haldimand.

Latest Developments in Concrete Roadways*

By H. S. Van Scoyoc, A. M. C. S. C. E.*

POSSIBLY no stronger evidence of the increasing interest in concrete road building could be offered than the fact that the registered attendance at the Second National Conference on Concrete Road Building, held in Chicago, February 15th, 16th, 17th and 18th, 1916, was more than fifty per cent. greater than that at the first conference, held in February, 1914. College professors, highway engineers and contractors spent four days in discussing committee reports, exchanging experiences, and outlining the most satisfactory methods for future work.

In 1914 more than 14,000,000 square yards of concrete paving was laid on streets, roads and lanes in Canada and the United States, a quantity just about equal to the total yardage laid previous to that time. In 1915 contracts were let for more than 19,000,000 square yards, but the extraordinary weather conditions interfered so seriously with construction work that the yardage completed amounts to about 15,250,000 square yards. From present indications more than 20,000,000 square yards will be laid during 1916.

Few changes have been made in the standard specifications, but there are certain tendencies that are well worth noting.

Reinforcing

There is increasing evidence of the value of reinforcing, but it must be admitted that no rational basis for determining the quantity required or the most desirable form has yet been devised. Experience seems to be the only guide.

Joints

The serious difficulty experienced in installing some of the earlier forms of metal protection plates and the discovery that improperly installed joints require practically the same amount of maintenance as unprotected joints has led to a very general use of unprotected joints. However, certain localities have found value in metal plates and, if the mechanical difficulties are overcome by the manufacturers, their use may increase.

The space between joints is being increased, especially where the paving is reinforced. The use of a poured filler has been almost entirely discontinued, except where a joint is used along the curb. A built-up filler consisting of a bituminous central portion enclosed in felt impregnated with bituminous material seems most satisfactory. The thickness is seldom greater than one-quarter of an inch.

Increasing stress is being placed on the necessity for careful testing of the cement, sand and stone. Sand and stone must be carefully inspected before going into the work and definite requirements as to grading, strength, resistance to wear, etc., must be met before the materials can be considered satisfactory.

Mixing

The unsatisfactory results from attempting to speed up the revolutions per minute have led to the setting of sixteen revolutions per minute as a maximum. Each batch should remain in the drum a full minute.

Sloppy mixtures must not be permitted. The proper quantity of water must be added to produce a concrete of rather stiff consistency.

The advance in the construction of mixers with chutes has been such that where sufficient slope is given to the chute concrete of proper consistency can be deposited in this manner. Where bucket and boom is used the overturning bucket has been found more satisfactory than the bottom-dump bucket.

Handling and Transporting Materials

Important savings can be effected, especially on the larger contracts, by the installation of labor saving devices. The value of any particular method depends upon the conditions to be met. Unloading machinery of the conveyor type and cranes or derricks with buckets are satisfactory. Tractors with trailers, motor trucks and industrial railways have all shown striking savings under advantageous circumstances.

Maintenance

The chief advance in this respect has been the use in some sections of a repair outfit mounted on a light motor truck. In some instances costs have been reduced one-third in this way.

Width of Paving

The desirable width of concrete for single traffic roads is ten feet, for double traffic roads eighteen feet and for triple traffic roads twenty-four feet. While the use of narrower widths may be justifiable in special cases, the great increase in the number of vehicles and the speed of the motor traffic that follow the completion of a good road usually lead to regret almost as quickly as the road is opened to traffic.

Good Roads in and around Ft. William

By R. R. Wright*

FORT WILLIAM besides being a distributing centre for Canadian West grain is the centre of a well populated farming district.

The Ontario Government has provided a good system of roadways to serve the farming district and the international highway to Duluth is well on the way to completion.

The district roads are for the great part graded earth roads, the main feeders being mostly gravel and some few broken stone.

In the City of Fort William there are about 71 miles of improved streets. The following is a list showing the mileage of road improvements to date in Fort William:—

	Miles
Asphalt Block Paving	1.672
Street Asphalt Paving	.595
Bitulithic Paving	.240

* City Engineer, Fort William, Ont.

Asphaltic Concrete Paving	2.159
Tarvia X Macadam	.073
Rocmac Macadam	1.485
Macadam (earthbound)	5.265
Gravel Streets	25.51
Graded Streets	54 10

The high cost of pavements has been the cause of a curtailed street improvement programme in the city up to the beginning of the war, and in 1914 it was decided to construct macadam roads at an average cost of $1.20 per square yard or approximately 57 per cent. of the average cost of asphaltic concrete paving at $2.10 per square yard. The results obtained are highly satisfactory and compare very favorably with a paved street.

The construction was carried out as follows: The surface was shaped and rolled with a 10 ton roller. A course of blue sandstone and slate consolidated to 8 in. in thickness with a 15 ton roller furnished the base. On this was spread a layer of 4½ inches of 2 inch gauge broken hard-trap rock, and 2 inches of binding (earth); the whole was consolidated by a 10 ton roller and well slushed with water to a finished thickness of 3½ inches. After the surface had become smooth, even, and to grade and camber a hose was played on and the surface cleaned off free from dirt. The road was then left to dry out and no traffic allowed on it. As soon as it was dry Tarvia B was spread by hand brooms and ⅜ in. hard-trap screenings (sufficient to conceal the tar) thrown evenly over the top. The street was then opened up for traffic.

After one month of traffic a second coat of Tarvia B and screenings was applied and the street completed.

There is no doubt that a reasonably cheap and durable road had been built. It is sanitary, waterproof and of high tractive quality.

When it is realised that such excellent results can be obtained by constructing macadam roads in a scientific manner there should be no excuse for the extra outlay upon pavements of different kinds. Moreover a macadam road can be dug up and repaired without any real injury being done so that a good road may be laid along a street without the extra capital outlay for sewer and water connections being necessary at the outset.

The general tendency under present circumstances is to curtail expenditures and economise. The macadamised road properly constructed and surface treated should therefore come into its own.

Road Maintenance in Quebec

(Contributed)

During the last three working seasons the province of Quebec has made tremendous strides in the matter of road construction, and it is to be hoped that the Government will not stay its hand until it has brought to a measure of completion the work it has set itself to do. When all the well settled portions of the province have been provided with a fairly complete system of improved rural roads, the saving to the agricultural community in time and wear and tear of horses and gear, will total a very large amount. The effect in retaining the young men and women in agricultural pursuits by improving their social and educational opportunities will also make for the solid prosperity of the province, the gains in this direction being more than the original cost of the improvements. Further, the effect upon local and tourist motor traffic is not to be overlooked.

One feature, however, appears to have been left out of consideration in the original scheme—a matter which demands the immediate and serious attention of the Roads Administration. This is the burning question of maintenance, or rather lack of maintenance. Unlike the Portland cement concrete structure, which improves with age from the day of its completion, a macadam road is at its best within a very short period after its completion, and thereafter is subject to decay and disruption whether used or idle. The elements conspire against it; those who benefit by it and use it often abuse it remorselessly, persistently, and with an utter disregard of its value and service to them. A farmer so shiftless and indolent, and a motorist so careless and indifferent of their respective machinery investments would be more or less of a scandal, to be apologized for by their neighbors and friends. But even without the inexcusable abuse to which it is usually subjected, a macadam road, no matter how perfectly designed and constructed, will not long remain in a satisfactory condition without proper maintenance, and in many cases will become utterly disreputable in a surprisingly short time. Money properly spent on maintenance is money saved.

The province of Quebec has now a respectable mileage of macadam and gravel roads such as any country might justly prize. Without any special publicity campaign the people have embraced the opportunity afforded by the Good Roads Act of 1912 so widely that the newly organized Roads Department has been swamped with such a volume of work as would well have staggered a much larger, more thoroughly organized and experienced combination. The absolutely necessary clerical work in the Department has constituted a tremendous burden upon the shoulders of the Deputy Minister and the heads of the various subdepartments, and we have reason to know that these responsible officials have worked overtime and nights constantly through the whole construction season in order to keep up with the great volume of work. Whether or not a re-organization or a simple extension of the personnel of the Department is necessary we do not presume to suggest, but we believe that the immediate organization of maintenance work on an adequate and efficient basis is imperative. If it be possible that the Government is not yet seized of the vital necessity of this work, and has not settled upon a plan of supervising and financing it, then it is high time their responsible officials, backed by the undivided and solid support of all interested in the ultimate success of the Good Roads Movement in the province, pressed it upon them in so impressive a manner as will compel attention and action.

The approaching Good Roads Congress in Montreal will give a timely opportunity for a thorough discussion of this important matter. We look forward to an official announcement being made that adequate measures for maintenance are being taken, failing which the Government should take this opportunity of memorializing the Government and supporting their suggestions by a strong deputation.

Better Highway Bridge Building

By A. W. Connor, B.A., C.E., A.M. Can. Soc. C.E.*

A good road and a poor bridge is an anomaly. In view of the large expenditure required for bridges in Good Roads systems, a discussion of some points in connection with bridge construction may be of interest to municipal bridge committees and road superintendents.

The Old Bridge

Most of the old bridges in this country are of wood, or of wood and steel, and were built for much lighter loads than now prevail. In general their days are numbered. The old steel bridges are mostly of the pin connected type, and are too light. Some of these might be rebuilt for shorter spans, with a new floor system, but putting in a new floor system and concrete floor in an old bridge, without a thorough examination as to its carrying capacity, is very risky. It is very unlikely to be capable of carrying a floor three times as heavy as its original one. The investigation should include measuring and examining all main members, especially adjustable ones, all joints, sizes of pins, arrangement of bars or pins and calculation of bending moments in same, examination for rust around pins, and, where water may collect, examination of shoe plates and rollers.

The New Bridge

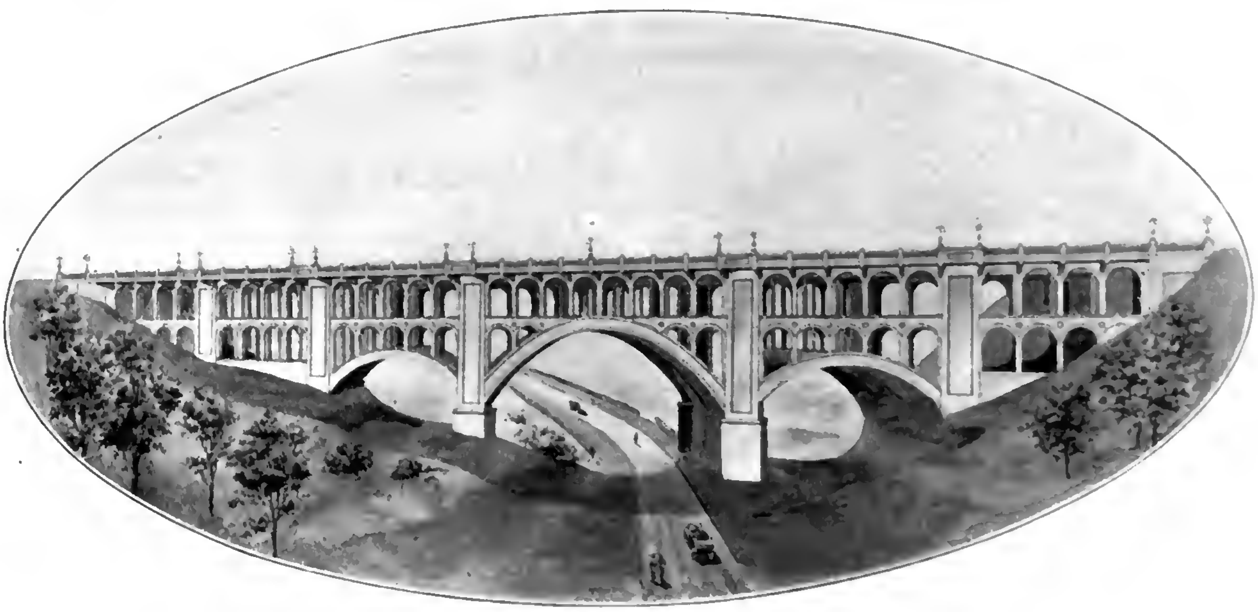
The kind of bridge, the span, the width of roadway and kind of pavement should be determined by local conditions, the nature of the foundations, waterway required and relative costs. The question of aesthetics should in future receive much more attention than it has in the pioneer days of bridge construction. The structure should conform to the surroundings, and be treated in a simple, not in an ornate, manner. Reasonable extra cost is justified in permanent structures, as "a thing of beauty is a joy forever," but a monstrosity is a perpetual eyesore.

The question as to how much more should be paid to obtain a permanent, instead of a temporary, structure may be figured out by computing the amount of the difference in first cost and any annual difference in maintenance at compound interest during the lifetime of the temporary structure, and equating it to the cost of a new one. Thus (if difference in maintenance be omitted) one might pay three-eighths more for a permanent structure, if interest be at 4 per cent., or one-third more at 4½ per cent., than for one lasting twenty-five years. In general one might pay more, as the maintenance charge would likely be less. As the premises are somewhat variable, the figures are only approximate. Exception is sometimes taken, however, to building for posterity.

Substructure

Abutments, wing and retaining walls, and piers are now nearly all built of concrete in mass, or of reinforced concrete. A small amount of steel is, however, advisable in the former, to prevent temperature or contraction cracks. The relative costs of concrete and steel at the site is the determining factor. Stone masonry is now generally superseded by the cheaper concrete. Steel cylinders, well braced together and filled with concrete may still be used, but lack the stability of heavy piers against jams of ice and floating debris. Wing and retaining walls are required to protect the earth fill in the approaches. They may be flared out and have sloping tops to suit the fill, or run back parallel with the road (forming a U abutment). The latter are now the most common, as they provide for handrailings, are readily lengthened if required, and have a better appearance. Where the embankment is high, and there is little risk of erosion, wings or core walls are built from the centre of the T abutment, serving to steady the same. Retaining walls should be tapered at least on the back, so that frost action will force the earth up instead of spreading the wall. Expansion joints should be made about every 25 feet to 30 feet and drainage from the back

* Bowman & Connor, Consulting Engineers, Toronto and Berlin.



Bloor Street Viaduct design in concrete, Rosedale section.

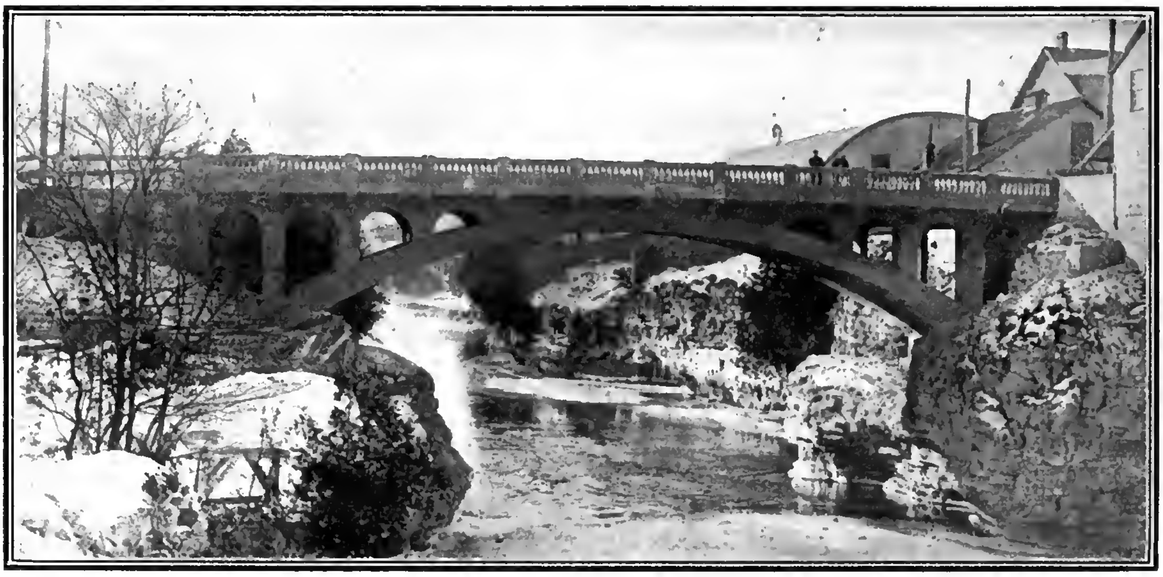
of the wall provided for. A coating of water 1 inch thick would exert as great pressure as if it were a mile thick. If the stream does not strike the line of the roadway square, it may be necessary to build the abutment or pier on the skew, or lengthen the span. This involves extra cost.

If solid enough foundations are not obtainable at reasonable depths, it may be necessary to drive bearing piles, or carry the foundations down to a solid substructure by means of pneumatic caissons, if the depth below water level is considerable. Wood and concrete piles (either cast separately or driven, or cast in position) are used. If provision against possible undermining is required, steel interlocking sheet piling or the wood piling of the cofferdam may be driven down.

Superstructure

The materials available are steel, concrete, masonry and wood. The last two are seldom used, masonry on account of its cost and wood on account of difficulty in getting suitable quality, and also on account of its temporary nature. Steel and concrete are strong competitors, both being excellent materials when properly used. Local conditions in all cases will determine which is the best to use. Concrete structures may be of either mass concrete or of reinforced concrete. The former is very much heavier than the latter and is seldom used for superstructures. The "raison d'etre" of reinforced concrete is the fortunate provision of nature that both steel and concrete have the same coefficient of expansion or they could not be used together. Steel is our best material for tension, and concrete in general best for compression, price considered. Concrete superstructures are of slab, beam or arch type, and occasionally cantilevers. On account of being cast as monoliths, concrete slabs and beams are generally continuous, a distinct advantage both for economy and rigidity. Arches must be built on unyielding foundations or provision made for taking up the thrust by steel embedded in the floor of the stream or through a concrete floor suspended from the arch ribs. The latter type of arch is getting to be very popular for spans too long for beams, and where small headroom for waterway is available. The arch has a decided advantage in appearance, if properly treated. The flat surface of the beam bridge, combined with the same in the abutments is very monotonous and requires panelling, or the use of an open type of handrail. An inexpensive type of the latter, consisting of separately cast railings and posts has been used by the writer on various occasions.

The generally accepted advantages of reinforced concrete are: permanency; small cost for maintenance; greater adaptability to architectural treatment; rigidity with lack of noise under traffic; employment of local labor in construction and keeping most of the money in the locality; the cement is made in Canada, while structural steel is all imported. These advantages are however lost unless all work and materials are in strict accordance with plans and specifications. Careless inspection is more disastrous to concrete than to steel. The advantages of steel are: it has no competitor for very long structures, or for long beams with limited depth; greater adaptability to all kinds of trusses and forms of construction; greater uniformity of material and consequent less danger from faulty inspection. It is the lightest structure that can be built.



Tower Street Bridge, Fergus, Ont.

The various types of steel superstructures are: beams, plate girders, trusses of various kinds, arches, cantilevers, suspension and swing bridges.

Length of Span

The span is determined by estimating the total cost of larger spans with fewer piers or shorter spans with more piers; by the location for the safest position for piers, and by the consideration of the amount of waterway required to take care of the greatest floods likely to occur. In general, the most economical arrangement is when the cost of substructure and superstructure are about equal. The determination of waterway necessary requires careful study. Enquiry should be made from old residents as to how neighboring bridges carry the floods, having regard to their spans and relative drainage areas. This can be supplemented by calculations from drainage area, maximum rainfall, runoff and slope of the stream. Maximum rainfall is subject to great variation and judgment is required as to how much waterway should be provided for, without undue cost. Allowance should be made for piers, causing jams of ice and floating materials, and for the fact that floods are apt to be greater now that the country is cleared and drained. It is unwise to reduce the waterway, as a municipality may thus be held liable by the courts for damage to property through floods.

Loads

The bridge should be designed to carry, with a factor of safety of 4, any loads likely to come on it, and to allow for future increases. There has been a rapid increase in the weight of traffic in recent years. It is expected that the maximum legal weight that may pass over bridges is to be twelve tons, so provision for fifteen tons at least should be made now for country roads.

Width of Roadway

Likewise, greater width of roadway should be provided on permanent bridges. Country bridges on improved roads should be 18 or 20 feet wide. The roads may be widened when required, but the bridge cannot be.

Duties of Engineer

It may be of interest to state the duties of the engineer. He should examine the site, test the foundations, make surveys and gather all available information. He should make estimates of the cost of the various propositions and advise as to the best. Prepare plans, making all calculations as to stresses and sizes of material required, stability of foundations, and so forth. Prepare specifications, instructions, with estimates of quantities for contractors and forms of tender. Advise as to the letting of the contract, draw the contract and prepare any further drawings required, or check over any prepared by the contractor. In the case of a steel bridge it is important that the detail joints should be of full strength (a matter often neglected). Inspect the work during construction and generally see that everything is carried out strictly in accordance with the contract. Issue certificates for payment, and for the final acceptance of the work.

The too common practice of asking contractors to submit their own plans should not be continued. The only way to determine the best tender is to have all bid on the same, unless the engineer reports on each plan (a rather laborious undertaking). It is assumed, of course, that the engineer is an expert and that his plans are both theoretically correct and practically feasible and economical in construction. Cheap advice, as in everything else, may be very expensive in the long run. There are a lot of weak bridges, said to be standing only from the force of habit. There should be some government inspection or regulation requiring county engineers to report faulty structures in all cases where human life may be risked.

A Satisfactory Paving Material

By J. F. Rhodes*

THE time has arrived when good roads must be built. The people are now educated in regard to road value from the standpoint of financial gain and the social advantages of the rural people. The graded earth or gravel road no longer fulfils the demands of traffic. These types provide only seasonal roads, which the public no longer desire. This condition makes it necessary to adopt durable roads of the hard surface type.

Formerly, farmers objected to hard surface roads, claiming they were too hard on horses' feet, but they now realize that a good hard surface road, usable every day in the year, is such a great advantage that this objection is negligible.

In adopting the hard surface road (that composed of stones) the road builders' problem is to select a binder that will keep the stones in place. The automobile, being driven by the rear wheels, soon loosens the stones in a loosely bound road, causing the road to ravel and rut. To overcome this trouble the binder used must be rigid and permanent. Portland cement is the only binder that meets these requirements.

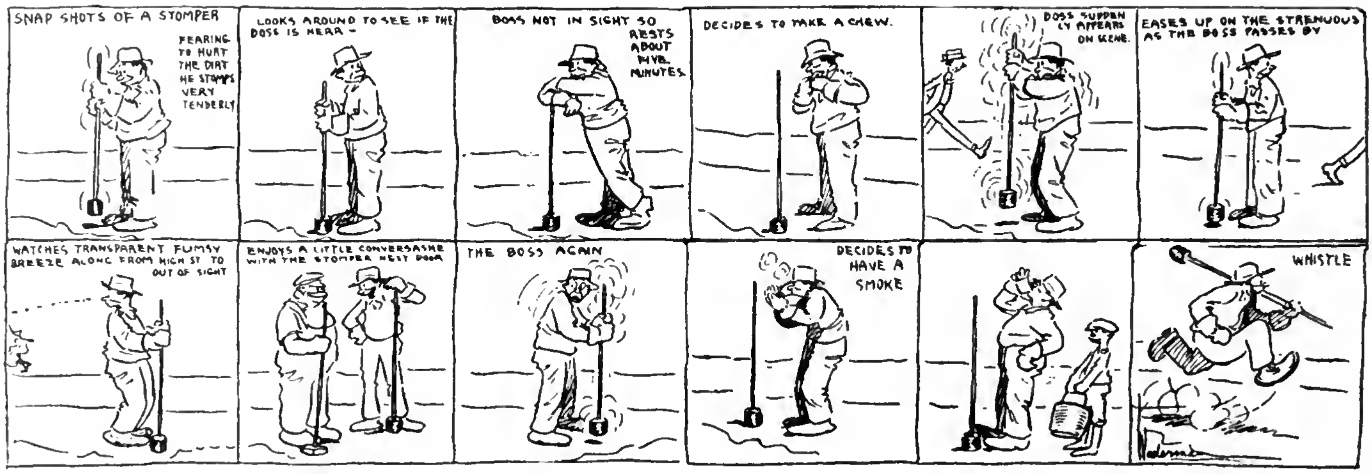
Quality

Portland cement concrete makes a road of the highest quality. It fulfils all the advantages required of a good road. By having a low crown, being smooth and non-slippery, it forms a road surface which is very favorable for travelling. As concrete wears very slowly by abrasion, a concrete road does not form dust or mud. The only dirt ever noticeable is that carried upon it from adjoining earth roads, which is readily removed by the wind and rains. Another valuable quality of a concrete pavement is its ease of maintenance. The contraction joints and any defects which may develop due to poor construction, are repaired with bitumen and sand or stone, and is a very simple operation. Repairs are also very slight, seldom costing over $25 per mile per year, and can be done without closing the roads to traffic.

Economy

Present conditions demand economy, not retrenchment, in expenditures. Money should be invested, not spent. Roads should be constructed which are economical when considered as investments. Investigation will show the high initial cost, cheaply maintained road, to be an economical investment, and the low initial cost, expensively maintained road, a costly expenditure. Concrete roads can easily be maintained for the life of at least twenty-year debentures for $50 per mile per year. Wayne County, Michigan, maintains their concrete roads for $25.50 per mile per year. The average yearly cost for maintaining the macadam types used in New York and Massachusetts is over $600 per mile, and these roads require rebuilding every ten years. Assume, for example, a concrete road surface can be constructed for $14,000 a mile and can be maintained for twenty years at a yearly cost of $50 per mile. The money to build the road is obtained by issuing twenty-year debentures. It is essential that the road be maintained every year, that the interest (assume five per cent.) on the debentures be paid yearly and enough money procured by yearly payments to rebuild the road in twenty years. The total yearly cost for this perpetual improvement is $1,173.40. A road of the macadam type can be constructed for $8,000 per mile, and can be maintained for ten years at a yearly cost of $500 per mile. Ten-year debentures are issued to build this road. The total yearly cost for this perpetual improvement is $1,536.04. The com-

* Publicity Manager Canada Cement Co., Ltd.



Good Roads Movements. By courtesy Municipal Engineering.

munity by building concrete saves annually $362.64 per mile. Choosing this road would certainly be economy.

Permanence

The permanency of concrete road is unquestioned Concrete paving which has been in use many years shows practically no signs of wear, as instanced in Bellefontaine, Ohio, where it was introduced in 1893, and Wayne County, Mich. Wayne County built 2½ miles on Woodward Avenue in 1909. This road has had very heavy mixed traffic. A census taken in 1913 showed a daily average of 320 horse-drawn vehicles and 2,290 automobiles. This road proves the permanence of concrete roads for all classes of traffic. The following paragraph is taken from their Ninth Annual Report, dated Detroit, Mich, December 20th, 1915.

"With the exception of the finishing up of the small stretch of brick roadway on Gratiot Road (let by contract) and 643 feet of gravel construction on the Ford Republic Road, all of our work is of our standard concrete construction and has been done under our own supervision and jurisdiction by our own forces. We have made no changes in our concrete specifications as we feel that the manner in which our concrete roads have stood the test of time and use during the past seven years and the small amount spent annually on their upkeep is ample justification for our adherence to the specifications we have evolved and the methods we have followed in their building. We have never taken up and replaced a twenty-five foot section since we have been building and developing this type of road, and its freedom from ruts and holes has permitted us to devote our energies and moneys to new work instead of resurfacing and repair work, which forms so large a part of the activities of other communities where a less durable type of road has been built at the outset."

Satisfaction

Concrete roads embody the three characteristics essential for a satisfactory modern highway: quality, economy and permanence. Permanent roads make the country property more valuable. Economical improvements make the people wealthier, and these advantages, combined with the high quality of concrete roads, completely satisfies them. When people are satisfied with an article they purchase it again. When the road builders give the public roads which are satisfactory the whole country will be lifted out of the mud in record time.

Canadian Brass Company, Limited

The Canadian Brass Company, Limited, Galt, Ont., are preparing a new catalogue covering their various products which will be of great interest to the trade. The products of this well-known company comprise corporation brass goods and plumbers' supplies. In connection with the first they make the well-known line of "Canadian" main cocks and curb cocks, lead unions, lead and iron unions and service boxes. Their curb and main cocks are equal to the best quality produced in Canada. They are all ground key work, i.e., after the cock body is reamed and the key or plug is turned on a lathe they are then put in what is called a cock grinder and every plug is ground to fit the body. This has to be done by a practical mechanic. When a perfect "ground fit" is accomplished the plug or key is thinly coated with a specially prepared grease that is guaranteed not to harden. The complete cock is then subjected to an hydraulic test, and if it does not show any leak, either through the metal body or around the plug, it goes to the field. What such careful work means to a corporation can be surmised if one considers that it costs more to dig up and replace a defective cock than the article is worth.

The lead and iron unions and service boxes of designs sold by this company for years have been universally accepted as high grade by many of the municipalities. In plumbers' supplies they also make the "Adanac" bath and basin cock. These two lines are probably as well known among the high-class plumbing trade in eastern Canada and parts of the west as any bath cock on the market. They are of red metal, carefully polished, carefully assembled and then nickel-plated, the majority of the trade buying them with porcelain index handles. These articles are subject to two tests, one when the casting is rough and the other when it is finished.

To fill out their line this company manufacture in the same careful way compression bibbs, sink cocks, drain cocks, comp. bath and basin cocks, gas cocks, round and straightway service cocks, either lever or tee handle, with the "Canadian" patent cap.

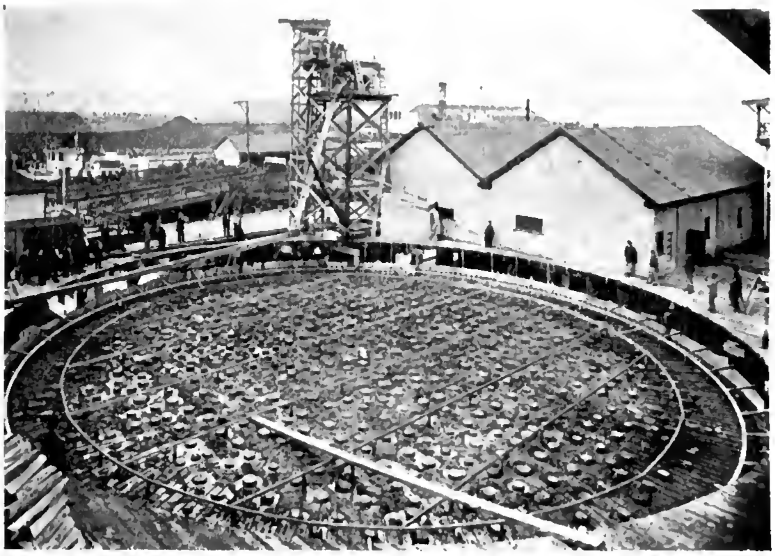
The plant of the Canadian Brass Company has been in operation in Canada for about nine years, and is splendidly equipped.

The Imperial Oil Company have awarded the contract to the London Concrete Machinery Company to supply two half-yard batch mixers to be used on their new plant at Regina.

Foundation and Fire Wall for Oil Tank

The accompanying illustration shows the foundation of a thirty thousand barrel oil storage tank at the Grand Trunk Pacific Railway wharf at Vancouver, for the Imperial Oil Company, Limited. The placing of the concrete was handled in a very economical manner, as described below:

After the piling was all completed, the hoisting tower was erected and the hoist motor put in place. The sheave supporting beams were made longer than usual and temporarily placed on the top of the tower and allowed to project over the mixer platform; the mixer and its motor were then hoisted in a few minutes by the hoist motor. The height of the mixer platform was so arranged that when the form-work for the fire wall was completed the mixer was at the correct height for discharging direct into buggies; at the same time it was of sufficient height to spout the concrete for the tank foundation, which is two inches thick. The tower was placed just over the outer edge of the wharf, so that the hoisting skip can be lowered to suit any stage of the twelve-foot tide. The scow was brought direct from the gravel pit, and on it was placed the cement which was received from the cement boat, which brought cement straight from the cement mills. The correct amount of aggregate and two sacks of cement was then dumped by wheelbarrows into the hoisting skip, which was hoisted and discharged into the mixer.



Concrete Pile Foundation for a thirty thousand barrel oil storage tank.

The specifications for the material for the foundation slab called for a mixture of 1-3-5. By measurement it was found that three cubic feet of sand and five cubic feet of gravel, when thoroughly mixed, measured seven cubic feet. At the gravel pit the correct amount of gravel and sand were discharged from different hoppers on to a belt and loaded on the scow. Care was taken, with the result that the material was very evenly mixed. The result of having the material mixed at the pit was that it was much more easily handled at the job and also one yard of mixed material equals one and one-seventh yards of separated material. From the above description it will be noticed that the only plant used was the hoist mixer, which is an important consideration when only handling a thousand yards of material. The contractors were the Dominion Construction Company, Limited, Vancouver.

Revision of Canadian Society By-laws

H. B. Muckleston, M. Can. Soc. C. E., has been nominated by the Calgary Branch and endorsed by the Edmonton Branch as one of the members representing District No. 6 on the Committee to consider the revision of the by-laws and other matters as set forth in a resolution adopted at the last annual meeting of the Canadian Society of Civil Engineers. Mr. Muckleston is a past chairman and a present member of the executive committee of the Calgary Branch. He has always taken an active interest in the affairs of the Society and will, if elected, make a valuable member of the committee.

Good Roads Men Want Duty Removed

The Manitoba Good Roads Association, with S. R. Henderson, president, in the chair, held a meeting in the Industrial Bureau February 24, at which the following resolution was passed:

"Whereas, it is to the interest of all residents in the Dominion of Canada to secure at the lowest possible cost the best road-making materials available, and as asphaltum oil and its by-products are valuable road-making materials and produced chiefly in the United States of America, it is the opinion of this association that this material should be admitted free of duty for road-building purposes; and it is hereby resolved to petition the Dominion Government to pass such legislation as will allow the free importation of such asphaltum oil or any other oil that may be used for road-building purposes."

It was decided to bring the foregoing resolution before the attention of the Canadian and International Good Roads Congress, which meets in Montreal, March 6, when W. F. Tallman will represent the Manitoba Good Roads Association.

Split-log Drag Competition

The question of split-log drag competitions was also discussed at some length.

Mr. A. McGillivray, highways commissioner, expressed the opinion that these competitions should be treated from a purely business standpoint and not entirely with the idea of winning prizes. It should be in the interest of all municipalities to maintain and improve their roads, added the commissioner, who stated that the government was ready at any time to help along the work in every possible way.

It was ultimately agreed to appoint the following gentlemen to wait on the Minister of Public Works regarding some definite line of action: Mayor Waugh, S. R. Henderson, A. C. Emmett and Reeve Haddow

Mr. Thornton on "The Development of the Mountain Park Coal Field"

Mr. N. M. Thornton, C. E., General Manager of the Mountain Park Coal Company, Limited, addressed the Edmonton Branch of the Canadian Society of Civil Engineers, at their regular meeting held on the 16th February. His subject was "The Development of the Mountain Park Coal Field." This property is located about 75 miles south of Edson on the Grand Trunk Pacific Railway. Mr. Thornton's address was illustrated by numerous photographs showing the various features of interest in the development of the field, and was greatly enjoyed by those present.

The Ontario Good Roads Convention

Most Successful in History of Association—Record Attendance and Splendid Enthusiasm—Important Topies Discussed by Best Men in the Business

THE 14th Annual Meeting of the Ontario Good Roads Association, which was held in the York County Buildings, February 22, 23 and 24, was largely attended, the number of delegates present from all parts of the province being the largest in the history of the Association. The total registration was upwards of two hundred.

President's Address

President S. L. Squire, of Watford, opened the proceedings with a short resume of the work accomplished during the year and outlined the aims of the Association for the future. Dealing with the expenditure of the people's money after the war, Mr. Squire favored the erection of highway memorials at different points throughout the province commemorating the work done by our Canadian soldiers in the present war and providing a means for employing a part of the great army of men and immigrants who will return to Canada after the victorious termination of the struggle. Even in a period of comparative financial stress like the present the work of provincial improvement should go ahead. Among other provincial works suggested by Mr. Squire was the building of a great through highway between Ontario and Quebec which should conduce to mutual trade and better social relations between the two provinces.

Limit Motor Loads

Mr. George S. Henry, M. P. P., secretary-treasurer of the Association, presented a bill to limit the weight to be carried on country roads and bridges by motor vehicles. This bill was referred to a committee for discussion and the wardens of the counties were appointed a special committee to forward legislation looking to the improvement of county roads.

Afternoon Session

Alderman J. G. Ramsden, together with Acting Mayor John O'Neill and Controller Thomas Foster, represented the city council and welcomed the delegates to the city. Alderman Ramsden, referring to the Toronto-Hamilton Highway, said that Mr. Gooderham had acted in good faith when he estimated the cost of the Highway at $600,000, but he was not a practical road man and must have been poorly advised. Mr. Ramsden expressed the opinion that before the Highway was completed it would probably cost $1,000,000, but whatever the cost, the work will have to go through now.

Knowledge Gained by Experience

Knowledge gained by experience was the warning taught by Sir John Hendrie, who spoke briefly, welcoming the Association, and, in passing, touching on the cost of the Toronto-Hamilton Highway: "I can speak feelingly of the cost of the Highway for I am a taxpayer in Flamboro and have to pay my share of the assessment. The province must soon spend millions on its roads; let us learn the lesson of the need of employing the best technical skill to estimate the cost of the work and supervise the construction."

The Lieutenant-Governor also spoke of the effect of good roads in improving social and farming conditions in the country and hoped that it would not be long until every road in the province would be greatly improved.

Why Counties Have Not Adopted County Road Systems

Mr. K. W. McKay, vice-president of the association, touched on the splendid system of highway laws as at present in force in Ontario, before calling on representatives of the counties, who had not adopted the good road system, to tell why they had not. Mr. John A. Best, M. P., speaking of the good roads system in the county of Dufferin, partly blamed the past relationship with Simcoe and Welland for not having gone into the matter. Mr. Best spoke forcibly of the good effect of better roads between the farm and the market towns to the farmer. Perishable produce is often spoilt, due to the fact that the farmer can't market it immediately on account of the bad roads. The system of statute labor should be a thing of the past. Under the present system some parts of the road are looked after better than others. War conditions need not seriously interfere with the establishment of a good roads system. If the statute labor system could be gotten rid of and the good roads system applied, the question would be generally solved. The question resolves itself into educating the people to the benefits to be derived. Until recently the country people have been very much prejudiced against the motors and have been averse to taking up good roads, but they are beginning to see the benefits of them and it is the duty of this association to further that education.

The item of the cost and the fear of the ballot box has led many government members to play safe rather than to take a stand on a question his constituents might not understand, even though it be ultimately for their own good. The Government pays 40 per cent. of the cost of new roads and the people are doing themselves a great injustice not to take advantage of the opportunity. Everybody pospers when the farmer prospers. It's up to the farmer to take advantage of the opportunities offered.

Situation in Elgin County

Mr. N. F. Cornell, of Port Stanley, explaining the situation in Elgin County ascribed the trouble to lack of education on the part of some of the county councillors and to the mistaken idea held by some counties, where material was plentiful, that they could build cheaper themselves than by contributing and working under the supervision of the Government.

Owing to the lack of sufficient data on the cost of roads in different counties, and the present financial crisis due to the European war and the eternal fear of the ballot box the system had not as yet been adopted by the county council of Elgin—the home of the Minister of Works and the Deputy Minister of Highways.

Dr. Meek of Port Rowan, past member of the county council of Norfolk, spoke of conditions there.

Some well populated counties have lots of good readily available material, with which to build good roads, while other sparsely settled counties lack not only the money but also the material. This with the advent of motor traffic, the present war and the inadequate education of the county councillors, who feel that good roads are a luxury rather than a necessity, prompts the wait-and-see attitude, and is the reason why many counties haven't been progressive enough to take the step in advance.

Don't Know the Cost

Warden McDowell, of Norfolk, in defending their "play-safe" policy stated that they weren't sufficiently informed on the cost of roads. Estimates had been submitted to them, which when gone into were only about one-third of what they should have been. The big item was the expense of materials which were not very convenient and necessitated long haulage.

People Need Educating

Mr. Anderson, also of Norfolk, in behalf of good roads mentioned the difficulties to be overcome, but stated that they could be overcome if the government would send a representative out to meet the people in a convention and show them the benefits to be derived.

Kent County Would Benefit

On behalf of Kent, a flat low-lying country, Mr. G. A. Frazer, of Thamesville, stated that no county would benefit more than Kent by a good roads system. The increase in property value would more than recompense for the extra taxation. But the people, now under a heavy drainage tax on account of the low flat nature of the country, could see nothing more than increased taxation. They have to be educated to the economical benefits to be derived in increased land values, due to better production, from better drainage, better transportation facilities, the increased comfort and the moral effect on the rising generation. Kent is somewhat in the position of the man who owned a gold mine but wouldn't spend enough to buy a pick and shovel to work it. Educate the people who may choose men whom they know will carry out their best interests regardless of consequences.

Want Concrete Roads

Mr. Hennigan, warden of Kent county, stated that, due to the flat nature of the country, the only roads they considered at all permanent were concrete, and so far they were marking time until they saw some examples of it.

Proper Handling of Highways

Mr. W. A. McLean, Deputy Minister of Highways, was loudly applauded when he rose to address a few remarks. The public highways have always been with us and always will be. Every man has to travel on them. The great problem of the people is, therefore, the proper handling of these highways. "On the highways of the province," said Mr. McLean, "we all meet on a common level. There is no fee charged. There is no ticket to purchase. There is a sense of ownership when a man is on a highway to be found in no other place in this or any other country. Let us make these highways the best we possibly can."

Before January 18, 1916, the Highways Department had never been able to present a fixed policy with regard to the aid they could extend. In 1910 the department was organized, which consisted of Mr. McLean and his stenographer. The government paid one-third of the cost of the construction of new roads. In 1913 a commission was appointed but nothing positive could be said in regard to their policy. In 1914 this commission handed in their report and in 1915 the act was passed, but up to January 18, 1916, nothing definite could be said as to when it would take effect. The first step taken on receiving definite authority was to send out a statement to all the county councils, showing how it would affect them. From the response the department feel it has been very beneficial and this first step will be followed up by others.

Answering a number of questions, Mr. McLean mentioned how difficult it was to state offhand the cost of any particular road. The trouble is, a county asks for the cheapest road under the regulations, as to cost. When it is started people recognize the room for improvement and demand it, with the result that the final part of the road may be twice as good as the initial part and consequently cost in proportion, but the people don't at once realize why. With good roads a farmer can produce a maximum and sell it immediately. But on poor roads he can only produce what he can transport. It is evident that the good roads will soon pay for themselves in return. Start in cautiously and work up to a system embracing all roads.

The system is not perfect, no human scheme known is perfect, but its good features are vastly in advance of its disadvantages. There are obstacles, but they have their compensation.

The European war casts its shadow, true, but we are all confident of the outcome and should go forward and prepare plans for the time when the war is victoriously over and the great army of men, and possibly almost as large a one of immigrants, come back. We owe them something and the opportunity of giving them employment on highway construction should be our aim.

Mr. McLean assured those present that the Department is always at their service, always ready and willing to meet and advise anyone in regard to the betterment of good roads.

Mr. Merrion spoke of the condition in Prescott and Russell, and the hope they had of effecting a bond between Ontario and Quebec.

Legacy for Posterity

Money wisely invested in providing good roads is one of the best legacies the people of today can leave to posterity, was the keynote of an address by the Hon F. G. Macdiarmid, Minister of Public Works. Good roads were not only a provision for the future, but they increased the value of the farm land and property in general. "Let us make our highways the best we possibly can. Good roads are necessary from an economic point of view whatever the cost."

Mr. Macdiarmid said that in spite of war, the campaign throughout the province to secure more good roads had made progress and it was possible even at such a time that legislation to help further with the work might be passed if the people of the counties would work together and prepare the preliminaries. There had been talk of the country passing through a period of stress and strain, but he believed that the stress was less today than 18 months ago. There was being exhibited by British people everywhere a feeling of confidence that was truly remarkable. Nevertheless it was not a time for reckless expenditure nor was it a time for standing still on the matter of securing better roads. The Government asked for their co-operation and hoped for a period of great prosperity and great immigration after the war and wished to be prepared for it. Highways, the best that could possibly be made, were essential to the success of the province, both from point of view of utility and economy.

The Benefits of a County Roads System

This question was discussed on Wednesday afternoon by a number of county representatives. Major Sheppard, speaking on behalf of the county of Welland, which was one of the last counties to come into the new system, referred to the benefits derived from the system. Since coming into the system Welland has made 162 miles of good roads in the last four years. Before these roads were improved the roads in Welland were about the worst in the province, but since improvement the difficulty is now not to get the people's consent to build more roads, but where to build them, each township clamoring for more in their particular division. Statute labor is unsatisfactory. The time has come when an organized system is necessary throughout the province. The cost of road building per mile is hard to determine without a systematic estimate of local conditions; every mile will cost different, depending on the convenience of materials, length of haul, number of culverts to be placed, and grades and hills encountered. In the county of Welland today, after a few years of Good Roads, there is not a dissenting voice.

Untiring Efforts of County Engineer

Warden Campbell, of Middlesex, one of the first counties to adopt a Good Roads system, in 1907, stated that their success was due to the untiring efforts of their county engineer, Mr. Charles Talbot. Up to the end of 1915, 240 miles of improved roads had been laid, and the programme for 1916 calls for 165 miles more. The cost of good roads in Middlesex is from $1,000 to $1,500 where gravel is convenient, and $4,000 for broken stone roads, the average cost being from $1,800 to $2,000 per mile. Mr. Campbell would like to see a limit put on the load for fast motor trucks. Due to the increasing traffic, these motors are breaking up the roads throughout the country.

Nothing But Praise

Mr. Wheelock, of Peel County, stated that after eight years of experience under the Highway Improvement Act the people of the county had nothing but praise for the system. People are insisting on good roads at whatever cost. In Peel nearly all the roads have been reconstructed, and the question now is mainly one of maintenance. The good effects to be gained from Government supervision, in which the Government pays forty per cent. on construction and new machinery and twenty per cent. on maintenance, should appeal to any progressive county.

The time is approaching when country traffic will be done entirely with motors, carrying an average load of from ten to fifteen tons, and roads must be built now to maintain this heavy traffic in the near future.

Increased Property Values

Mr. W. Anderson, Prince Edward County: After nine years under the county system land values in Prince Edward have increased at least 25 per cent. This should be a big item in influencing those counties not yet under the system to take it up. The cost in Prince Edward averages from $2,200 to $4,000 per mile, depending on the kind of land over which the road is built and the convenience of the building material.

Wentworth County

The county of Wentworth, which receives some of the heaviest traffic of the province, due to the fact that it lies in the path of traffic passing between Detroit and Niagara Falls, has been working under this system since 1902, and have spent about $378,000 on county good roads. The system now is in very good shape, 153 miles of improved roads having been laid. The social and moral advantages claimed for this system, and the increased value in land, are great assets to the county. When it is considered that 240,000 acres have increased in value from $2 to $50 an acre, one will see the good effects of such a system.

Cost $1,500 to $4,000 a Mile

Mr. Pugsley, of York County, the pioneer county in Good Roads systems, spoke of the attempt made ten or twelve years ago to have good roads over all York, and the subsequent division into north and south when the system was turned down—the southern portion adopting the system, and the northern staying out.

Good roads in York have cost from $1,500 to $4,000 a mile. The fact that most of these roads lead to Toronto, and the excessive nature of the traffic, has necessitated a very permanent form of construction. About 115 miles of roads have been constructed, at a cost of approximately $600,000.

North York, realizing the advantages of the new system, were unanimous at the last meeting of the council to adopt Good Roads. Mr. Pugsley would like to see all the counties adopt this system, and have good roads from one end of the province to the other. It would not only be an economic benefit to the people, but also a benefit from a military standpoint, due to the great advantage of rapid transportation.

Hastings County a Pioneer

Ex-President Vermilyea, of Belleville, representing Hastings County, which was one of the early pioneers in the good roads movement on which it had spent two millions of dollars before the Government had made a grant, advised other counties to follow suit. Begin now on roads nearest the respective market towns and progress year by year as finances would allow and forget that it was a stupendous task, was Mr. Vermilyea's advice, for in years to come, he said, the saving in horseflesh, labor, and increase in farm values would soon repay more than the roads would cost.

Land Values Increased 25 Per Cent.

Mr. Willoughby Anderson, Prince Edward County, said his county adopted a good road system nine years ago, and in farm centres the land values had since increased as much as 25 per cent.

Good Roads Sign of Prosperity

Mr. C. R. Wheelock of Dufferin County, expressed a similar view, and advised the counties to build their roads to meet heavy traffic for heavy motors would be the chief means of transport in the near future. If the counties, still years behind the times, would adopt a good road system the townships would follow suit. Good roads were a sure sign of the alertness and progressive spirit of the farmer.

Financing Good Roads

Mr. K. W. McKay, St. Thomas: Good roads are investments and must be paid for; there are no bargains in road building. The question resolves itself into one of legislation and our present laws are evidence of our aim to provide better equalization; to derive the funds from the proper source. That the Highways Improvement Act has only been adopted in one-half of the counties suggests that increased legislation is needed. With the improved county roads, both the country and city resident benefits by the results of improved transportation facilities.

Mr. McKay believed that the present legislation is somewhat inadequate. Townships should pay according to the benefits derived, and should assess the land as they derive benefit from the road. A man on a back road does not get as much benefit as the farmer living on the improved highway. The assessments should be made on benefits derived rather than on frontage. Under the new regulation the government pays 20 per cent. on maintenance and 40 per cent. on new construction, also 40 per cent. on new machinery. Provincial aid is extended in the case of country roads, suburban roads and main highways—that is between cities. The Department encourages the adoption of the system and the appointment of road superintendents.

Highways are classified by the traffic thereon, and the ways in which they are improved. Maintenance is the keynote of a good roads system. It should start as soon as the new road is finished. Counties carry on their road improvement financially in three ways—first, by an annual levy, which is employed by seven counties; second, by a combination of annual levy and debenture issues—three counties employ this system—and last, by debenture issues alone, which seems to be the popular system, ten counties having adopted it. The time limit of the debenture is set by the department. It would be unwise to extend them beyond the reasonable life of the highway.

In conclusion Mr. McKay said, (1) Give the counties time to study the system and inaugurate it; (2) Have proper provision in the Highways Act for the township to pay in proportion to the benefits derived; (3) Have the Department supervise the issue of debentures and (4) Build the best road possible, as the most expensive first cost highway is the cheapest in the end.

When Are Gravel Roads Profitable?

By Chas. Talbot, C. E.*

A good road gravel is composed of hard and tough pebbles and stone of different sizes and sufficient sand and binding material that when consolidated in position on the road it will form a solid mass.

Where large stones are found in a gravel pit they should be removed before loading the gravel and where a large proportion of the gravel is composed of large stone the whole of the material should be run through a crusher and screened, the excess of sand resulting from the screening may be placed in the base of the road with the larger stone and on top of this the smaller stone filled with sufficient filler from the small screen. Where gravel deposits have not sufficient binder to consolidate the necessary binder will be produced by passing the material through the crusher.

In the construction of the gravel road the subgrade should be firm and the gravel deposited and rolled in layers of four or five inches and finished by using a moderate amount of rolling and watering. A gravel composed of large stone and fine sand is very objectionable and results in inferior work. Gravel composed of small pebbles coated with an iron oxide or a clay binder sets readily and produces a very serviceable road for light traffic.

The more difficult it is to consolidate the gravel the harder and more durable is the surface formed. The gravel that has an excess of binder dissolves easily under traffic in wet weather and ruts are formed; is may however be restored with a grader or log drag if used at the proper time. This cannot be done with the better class of gravel and the ruts and depressions must be filled with fresh material.

In the construction of gravel roads the roller is useful to consolidate the grade and roll the gravel sufficiently to form a reasonably firm surface. After this is done I am inclined to the opinion that further rolling is not beneficial as it apparently requires the action of the traffic upon the small stone to produce the binder that results in its final consolidation.

The selection of suitable gravel, the treatment necessary and the quantity used must all be decided by the person in charge of the work and his decision will depend upon local conditions. When traffic is heavy and liable to increase gravel should not be used in new work.

Upon highways adjacent to cities such as Toronto, Hamilton and Buffalo and throughout the counties connecting these cities, traffic conditions are quite as congested as they are on city streets. Consequently they and all such roads must be treated in a class entirely by themselves and as they at most represent less than 2 per cent. of the road mileage of the Province they are of little importance to the people as a whole except as an object lesson representative of the conditions that will obtain in the near future through a much wider area.

Eight per cent. of the total mileage has a traffic of less than 375 and more than 100 vehicles per day and 90 per cent. has a traffic of less than 100 vehicles per day.

Earth and sand roads compose some 19,000 miles of the total road mileage of the organized portion of Ontario, 20,000 miles are represented as gravel roads, 4,000 miles stone roads; the balance, some 12,000 miles, are unimproved.

From the foregoing you must conclude that while the problem of meeting conditions where traffic is congested is large and ever increasing the subject affecting the greatest number of people of Ontario exclusive of those residing in the cities is the one that deals with the long stretches of country roads where traffic is comparatively light and less expensive con-

* Road Engineer, Middlesex County

struction answers the requirements demanded of the roads.

Convenience of Material

Where material such as stone and gravel must be transported over the railways or by wagons or tractors over long stretches of roads for the original construction of the road no material progress has been made, the cost being considered prohibitive.

On the other hand marked improvement has been made in every instance where gravel, stone or rock is available within hauling distance of the highways.

As the people who control the matter consider the importation of material for the road crust too expensive, the question resolves itself for the present into a consideration and treatment of the materials available and a systematic use of them to produce economic results.

Where earth roads obtain because of lack of metal the roads will remain unsurfaced until the ratepayer decides he can afford the cost of importing stone or gravel for their improvement, or some method is discovered whereby the clay and sand may be converted into a suitable road crust.

With the gravel road, conditions are different; already long stretches of these roads are constructed and are in serviceable condition, and with a Provincial Department of Highways to supervise and direct the organization plans for the systematic improvement in both townships and counties marked advancement must necessarily follow and at least the foundation work of a complete system of highways in the near future will be constructed consisting of properly formed and drained grades strengthened by the application of such local material as is available and for the time being constituting both the base and wearing surface of the present highway but which will in the future constitute the foundation for the more expensive road surface which will be demanded as the country increases in population and wealth.

For the present however we are compelled by the magnitude of the work and the comparative undeveloped state of the country to utilize the material immediately at hand and with them in so far as possible meet the problems confronting us in the matter of the constructing of new roads and the improvement and maintenance of the old.

Drainage

As this paper is not supposed to treat with drainage or the construction of the grade I must assume that in all cases before gravel is placed the water line has been lowered to at least 3 feet below the top of the grade and adequate provision made by a proper under drainage system to keep the sub-grade free from water; failing this no satisfactory results will be obtained by placing gravel or stone on the road.

I stipulate the use of under drains because the use of an unguarded open drain upon the highway is unlawful and useful only to carry off the surplus water from the adjoining lands. Farmers have long since learned the open drain is serviceable only as an outlet for his under drains and the road Superintendent will after a series of expensive experiments discover the open drain on the highway is useful and jealously guarded by the farmer for the same purpose.

Assuming the drainage is good and the grade properly constructed you have what constitutes the only foundation required for a light traffic. A surface coat of best available gravel or stone is then applied using from 800 to 1,800 c. yards per mile; this consolidated with the road roller or lacking a roller consolidated by the traffic with repeated leveling, produces a road that will be serviceable and that will be maintained with an expenditure of $50 to $100 per mile per year.

Such a class of construction will meet the requirements of roads where traffic does not exceed 100 vehicles per day and represents approximately 90 per cent. of the total mileage. There remains however approximately 8 per cent. of the total mileage with a traffic from 100 vehicles to 350 vehicles per day which is a more serious and difficult problem.

Here as in the former case the drainage and grade must be considered the most important part of the foundation. In order however to sustain the increased number of heavy loads, the most destructive auto traffic and the excessively loaded and rapidly moving auto truck, the foundation must be strengthened by a depth and width of metal suitable to the traffic requirements. Where traffic exceeds 200 vehicles or where the greater portion of the traffic is composed of heavy loads a double track road should be constructed say 12 or 14 ft. wide while on the roads of less travel an 8 or 10 ft. road will suffice.

Subsoil

On the subsoil will depend the depth of metal required. Sand and gravel subsoil will require a lighter base of gravel while open loam and certain clay subsoils require a greater depth. It is impossible without extensive experiments to ascertain the approximate depth required. This however, is a matter of no serious import as an additional depth may be added where conditions demand at a price equal to the cost of the original construction.

The most economic plan would be to err on the light side provided the defect is detected and remedied before the gravel is forced into or mixed with the subgrade which is a matter easily detected and prevented. The piling on of gravel or stone to an excessive depth without first ascertaining what depth of metal is necessary is a matter where thousands of dollars may be wasted without a possibility of a return for the expenditure.

After a roadway has become firm and ceases to yield under traffic only sufficient new metal should be used to maintain the crown to its original form and fill the depression that may develop. Such a process will require an expenditure of $75 to $150 per mile per year.

An old gravel road which has been properly constructed and reveals a considerable depth of gravel in the foundation should be repaired by removing the shoulders and adding a sufficient amount of gravel to complete the crown. Where the old deposit of metal has worn excessively or is mixed with the sub-grade better results will be obtained by adding sufficient metal on top of the old gravel to restore the crown. The gravel required to construct a road 12 ft. wide at $1.00 per cubic yard will cost approximately $3,000 per mile. A road 8 ft. wide will cost about $2,000 per mile and the resurfacing of the worn road about $1,000 per mile.

Until this year no systematic attempt has been made to encourage or organize an effort looking toward the maintenance of country roads. This year the legislature has provided that where a systematic plan is adopted by a county they will contribute 20 per cent. of the cost, which is one half what they pay toward construction.

The maintenance of a highway is admittedly more important than construction or re-construction, consequently were the larger percentage paid for maintenance and the smaller for construction or had they been placed on equal basis we would conclude due consideration had been given the matter before the final decision was made and a premium placed upon the neglect of the more important phase of the work.

Where traffic exceeds 250 to 400 vehicles per day and consists in part of auto trucks, a gravel road will not maintain its binder and must be replaced by a better class of road. Where such conditions have developed there is no hesitation upon the part of the County Council to assume the responsibility and construct the new and more expensive road.

The ease with which such men adapt themselves to the changed conditions and decide on the large expenditures necessary to finance the change is accounted for by the fact that they have through the construction of the lighter class of road and its maintenance become accustomed to the expenditure of comparatively large sums of money and this has served as an education to train them for the larger expenditure. This is in marked contrast to the people living on the earth road who have been inactive and their inactivity has not only left him without education along such lines but has created a condition within themselves which they are incapable of overcoming. When told by an outsider or by one of their companions who has remained normal under such conditions how they may receive and finance a scheme to bring them out of their difficulty, they will not believe, or if they do, they sicken at the thought of the expense like a young child who has received an overdose of pap. They realize their weakness and express a desire for strength. If they take their nourishment in increasing quantities they will soon be able for a full meal of solid food in the form of gravel stone or concrete. Their first dose must necessarily be a County road Bylaw.

Gravel roads are profitable so long as they satisfy the demands of the people who use them and can be maintained for less than the interest on the cost of a new and better class of highway.

When is Crushed Stone Profitable?

By Lucius E. Allen, C. E.*

THE subject, "When is Stone Profitable for Roads," which I have been asked to speak upon this morning is one which if thoroughly treated in detail would require considerable time, and in the time allotted for introducing this subject for discussion, I can only outline some of the more important points with reference to the use of stone as a material for road construction.

The use of stone for the construction of ordinary highways is of ancient origin, the remains of stone metaled roads having been found in Egypt dating from the time of the Pharaohs. The Carthaginians also used stones bound with sand, and the so-called Roman roads were mostly built of stone laid in various ways, but probably the modern methods of using broken stone and afterwards consolidating by natural or artificial means dates from the time of those forefathers of Good Roads McAdam and Telford in England, and Tresaguet and Polonceau in France.

The systems of road construction as designed and introduced by Tresaguet and McAdam differed only in the matter of the foundation. The system as introduced by Tresaguet consisted of a stone foundation six to eight inches in depth formed up of stone blocks laid on a bed whose surface was given the same camber as the finished roadway. These stone blocks were placed by hand and the crevices filled with stone chips well hammered in. Upon this stone foundation a layer of crushed stone was placed of from four to six inches in depth and thoroughly rolled, or consolidated. In modern practice the surface metaling is usually put down in two layers, each layer being well rolled, with the addition of fine screenings to act as a binder. This type of roadway, while being rather expensive in first cost, if properly constructed has been found to be a very durable type of roadway and well adapted for certain localities.

On account of the heavy built up stone foundation which takes up the impact and shock upon the metal surface from heavy traffic, this type of roadway is consequently well adapted for roads where the character of the traffic consists of heavy moving loads such as trucks, tractors, etc. The metal wearing surface when worn down can be renewed many times without extra labor or material being expended on the stone foundation.

McAdam's system is essentially the same as the French system except that the stone foundation is omitted, the roadway consisting of a more or less dense layer of metal of varying sizes held together by a binder of fine material and well rolled. Polonceau, a French engineer, in 1829 improved upon McAdam's system of construction by first making use of road rollers to compact and consolidate the metaled surface.

Undoubtedly the macadamized road where the natural sub-soil is good is the most economical type, as the wear on a roadway is largely on the surface, and as long as the metal surface is kept in good repair there is no necessity for an expensive stone foundation similar to the original French system. Where good gravel is difficult to obtain and a suitable crushed rock is available, a road surface composed of from four to eight inches of crushed stone, placed on the old gravel or earth roadway, after scarifying same, and well rolled down with a road roller is for our ordinary highways the best type of roadway, provided they are properly constructed and the best material used.

While a roadway constructed in this manner may be adapted for districts where the traffic conditions are not too excessive, it is no doubt advisable where the conditions are favorable and warrant a more permanent road surface to adopt some form of bituminous binder or carpet which will bind the stone aggregate into a more or less solid mass that will withstand the hammering action of heavy traffic.

Where the motor traffic is considerable—and few of our main highways are not now extensively made use of by motor cars—a treatment with road oil on the surface will greatly increase the durability of the roadway, and decrease the dust nuisance.

It is not, however, within the scope of this paper to enter into a discussion of tar or bituminous bound macadam, or carpeted stone roadways, or oil treated roads, but rather to refer to several points which

* Engineer Hastings County

should be, and many times are not, carefully considered in selecting stone for roads.

Quality and Kinds of Stone Adapted for Roads

Too little attention is often given to an examination of the kind and quality of the stone which is to be placed on our roads. There are many instances where a crushed rock has been carelessly selected and used, which in the end proved to be far inferior to a good gravel. Within the Province of Ontario occur a great variety of igneous, sedimentary and metamorphic rocks some of which make excellent material for road metal, while others which may appear firm and hard superficially soon weather or rapidly deteriorate under traffic.

Within the past few years many of the Highway Departments of the principal countries in Europe and in America have realized the importance of a systematic examination of those rocks best adapted for road construction, by establishing testing laboratories for this purpose.

To France must be given the credit for first establishing in 1878 a laboratory for testing road materials. Colonel Crompton, Consulting Engineer to the British Road Board, established a few years ago at Teddington, England, an excellent testing laboratory for determining the relative value of various road building materials and designed and put in operation a machine which subjects various types of roads and pavements to the actual conditions found in all classes of highway traffic, and most valuable information has been secured from the results of his work.

The Provincial Department of Highways of Ontario, under the efficient direction of Mr. McLean, is also equipped to carry out the testing of rocks for road building.

In addition to a chemical analysis of a rock, which in many cases will indicate its suitability, there are four essential physical tests which should always be applied in determining the relative suitability of the rock. These tests when applied will show:—(1) The relative hardness; (2) Toughness; (3) Abrasiveness, or resistance to wear; (4) Cementing value.

It is obvious that a rock which best withstands the destructive agencies of the atmosphere, water and the severe wear and tear of traffic is under normal conditions the most economical to use, and in many cases it will be found that the use of a rock which happens to be in close proximity to the work, and therefore costing much less for haulage or transportation, may yet be far less economical than a rock found many miles distant.

A determination of the hardness of a rock will indicate its ability to withstand the displacement of its surface particles by the friction caused by steel tyred vehicles.

The relative ability of a rock to resist fracture from the hammering action of rapidly moving vehicles is a measure of its toughness.

The abrasion test will show the relative degree which a rock will withstand wear, or the grinding action of the steel tyres and the steel caulks of horses' shoes.

The relative degree to which a rock dust will cement or hold the rock particles together, thereby forming an impervious and smooth road surface, is its cementing value.

Just as a poorly burned or porous clay brick will absorb a large amount of water, thereby tending to disintegrate the brick structure, so a soft and porous rock will tend to disintegrate under the continual action of water and frost.

As a general rule the granites are much harder than the limestones, but on the other hand have much less cementing value. There is no doubt that for toughness and ability to withstand severe wear the trap rocks are the best for road making material, however on account of the excessive first cost of trap rock in many localities the use of crushed granite, field stone and limestone prove to be the most economical in practice.

As a general principle it may therefore be stated that a rock that combines to the highest degree the properties above referred to is the best adapted for road construction. The following record of a large number of rocks tested by the United States Bureau of Roads will serve to show the comparative values of the various rocks used for road construction.

Table

Showing the average results of all of the tests conducted on characteristic road building rocks up to Jan. 1, 1912, as carried out by the U. S. Department of Roads.

	Hardness	Toughness	Cementing Value	Per. cent of Wear
Limestone	14.4	8	54	5.2
Sandstone	15.0	12	62	5.7
Granite	18.5	12	18	4.5
Trap Rocks. . .	17.6	17.4	95.4	3.1

Construction and Maintenance

The first essential in the construction of a stone roadway is to provide proper drainage. It is obvious that if water is allowed to soak into and penetrate the soil foundation of the roadway, the road crust will soon be disrupted, the result being that the lower portion of the stone crust penetrates into the wet soil and gradually the soil becomes mixed with the stone, causing holes and eventually almost complete destruction to the original roadway. Good drainage can be secured by keeping the earth shoulders well down, and providing side ditches of sufficient depth and width to quickly remove the water.

Many times the lack of suitable culverts to carry the water from a higher to a lower level underneath the roadway is the cause of serious destruction to the road. In soft and boggy soil it is necessary in some cases to construct lateral drains, leading from the center of the roadway to the side ditches. Proper and ample road drainage is just as essential as farm drainage and the initial cost will soon be repaid in the increased life of the roadway.

Grades and Crown

As the ordinary constructed roadway surface is not impervious to water proper crown should be given to the road to prevent water settling on the road crust. Ordinarily a crown of one-half to three-quarters of an inch per foot is sufficient for macadam roads.

In the construction or reconstruction of so-called main trunk roads reduction of excessive grades is also important. The increased hauling power of heavy loaded vehicles due to decreased grades on highways will in many instances soon repay the initial cost of the reduction of the grade.

Too much care cannot be exercised in rolling. It should commence at the edge and work towards the center, the roller at all times traveling parallel to the center line of the roadway. With proper rolling the consolidation of the crushed stone surfacing should be equal to about 33 1-3 per cent. of the loosely deposited stone.

The size of crushed stone best adapted for road metal depends upon the type of road under construction. Usually larger size stone up to three inches may be used in the bottom or foundation course, and the finer stone for the top courses. The aggregate should be so graded as to furnish sufficient sizes to consolidate into a typical mosaic under compression. Sufficient fine stone screenings should be used on the finished road surface and watered to thoroughly seal and fill the voids in the compacted metal.

The question of maintaining our stone roads is of almost greater importance than new construction work. Much thought and attention has been given the matter of how best to keep our roads up to a high state of repair. The use of narrow tyred heavy vehicles should at once be prohibited. The cutting action upon the metal road surface of such a vehicle passing over a roadway during wet weather is one of the most destructive agencies to roads. Once a rut is formed, water immediately collects in the rut and penetrates transversely throughout the road surface, thereby hastening the disintegration of the road surface.

Two general methods of maintenance are followed in various countries, namely the "Patchwork System" and the "Periodic Renewal System."

It is truly said that maintenance should start as soon as a roadway is completed. The "Patchwork System" as generally carried out involves the constant and immediate repair of any portion of a stone roadway as faulty spots develop. It can be carried out by a system of patrols, who become responsible for a given length of road section. The work of repairing and filling holes and bad ruts should be done by men familiar with and experienced in the work. The old adage "A stitch in time saves nine" aptly applies to road repair work. In the patrol repair system suitable quantities of crushed stone should be kept at intervals on each road section. One man and a horse and cart can keep in repair a considerable length of roadway. As to whether such a system of road maintenance would work out to the best advantage in this country is not within the scope of this paper.

The "Periodic Renewal System" is based on the principle of a general resurfacing of a given roadway as soon as it becomes badly worn. The disadvantage of the system is that it requires a much larger amount of material to complete the resurfacing of an entire roadway. The unit cost of carrying out the work is no doubt less than in the "Patchwork System" as materials can be handled on a larger scale and the work is concentrated at one point.

It would appear that possibly a combination of these two systems could be worked out to better advantage in this country than either the one or the other.

As much depends on the amount and character of the traffic over a given highway as to the amount and depth of road metal and foundation that should be used, it is essential that a careful census be taken extending over a considerable length of time. As traffic, especially automobile traffic, will seek the best road, it is necessary to make due allowance for the probable area from which new traffic will originate.

Conclusions

In concluding the introduction of the subject of crushed stone for roads, it may be stated that no hard and fast rule can be laid down as to when stone can be used for road construction in general, neither can any fixed figure be given for the cost of a macadam roadway, as the cost of labor and materials will vary greatly in different localities. It may be stated, however, that in districts where suitable stone adapted for road metal is found, it is generally preferred to other material such as ordinary untreated bank gravel.

The uniformity of crushed stone as compared to natural gravel is no doubt an advantage, as bank gravel has been laid down in strata the result of glacial drift or sedimentation and it is difficult to always obtain sufficient uniformity to ensure the necessary binding and wearing properties for road construction.

The salient points to be considered in the construction or re-surfacing of a rock metaled roadway are:—

1. Careful examination and selection of the quality of the rock, taking into consideration the relative durability and initial cost.
2. The proper preparation or scarifying of the foundation.
3. The drainage of the foundation by means of ditches, drains or culverts and the removal of the earth shoulders to secure surface drainage.
4. Consideration before construction is started of the estimated amount and character of the traffic, upon which the type of construction can best be determined to meet existing or future traffic conditions.
5. Due attention to the grade and crown of the roadway to ensure uniform wear over the traveled portion of the roadway.
6. After construction is completed the immediate and constant attention to repair and maintenance, which will add to the ultimate life of the highway.

In many sections of Ontario it will be many years before the density and wealth of the population will be such as to warrant the construction of so-called permanent highways, and the use of the cheapest and most abundant natural road material such as gravel and stone will have to be resorted to, so that the methods of constructing stone metaled highways will continue to be of greater importance to a larger number of people than the construction of more expensive highways.

It is quite possible that as these materials and methods are further investigated the present methods will be so improved upon that for a majority of our roads, the use of crushed stone will continue to be the predominant road building material.

When is Bituminous Material Profitable?

Mr. E. A. James, County Engineer for York, states that in some parts of York County the country roads, as far as traffic goes, are regular city streets; on some roads as high as 200 vehicles per hour and 12 trucks from 12 to 16 tons, pass per hour. Under such conditions brick laid on 4½ in. concrete foundation, 18 ft. wide, with stone shoulders on an old 24 in. stone foundation, has proved the most satisfactory. This road in 1911 cost $22,000 a mile and, after four years wear, has only cost $2.00 to $3.00 per mile maintenance. Rocmac pavement, a preparation of silica, with limestone dust, forming an insoluble chemical compound, has been used to good advantage on some roads in York county, giving much better service than water bound macadam.

In 1913 the county of York commenced building with bituminous pavement on old macadam roads, which had about 9 in. of stone foundation. The old macadam was first thoroughly cleaned with a rotary brush, picked and swept and a four inch layer of 2 in. limestone laid and consolidated. 1¼ to 1½ gals. of bitumen per sq. yd. was then sprayed on by pressure tank and any excess taken up by stone chips, after which the whole surface was consolidated to 3 in. in depth. ½ to 1 gal. of bitumen per sq. yd. was then applied and the surface sanded and rolled again. The average cost in 1913 and 1914 was 62c per sq. yd.; stone costing $1.05 per ton, labor 20c an hour and teams 45c per hour. On old gravel roads of 4 in. to 9 in. thickness, which are being subjected to increased traffic, it is considered unwise to resurface with gravel, but rather to reshape the road with a 5 in. coat of 1¼ to 1½ in. stone with some tarvia, similar to a water bound macadam construction. This costs about 85c to $1.00 per sq. yd. On grades over 7 per cent. it is found extremely difficult for heavy traffic to pass up on bituminous surfaces, without sanding. Brick is passable up to 8 per cent. grade without sanding. The advantages of these surfaces is the elimination of dust—present in water bound macadam roads. The apparatus needed in the penetration method is very simple and very cheap. In the mixed method, of mixing the material and the bitumen, then placing, the apparatus is more expensive, but the type of road is also superior to that built by the penetration method. The cost for the latter method is about ten per cent. in advance of the penetration method. Mr. James, in replying to the questions of bridges rutting and the effect of frost in spring on surfaced roads on clay soils, said that he had found a mixture of bitumen with ¾ in. stone thoroughly compacted in the road rut to give thorough satisfaction. Improved roads have always been well drained and being waterproof have kept dry and have given no trouble.

When is Concrete Profitable

Mr. H. S. Van Scoyoc, chief engineer of the Toronto-Hamilton Highway, addressed the convention on "When are Concrete Roads Most Profitable?" Mr. Van Scoyoc spoke of the various items to be carefully considered and properly balanced in deciding upon any particular type of surfacing for any locality. While improved roads create values that cannot be measured in dollars and cents, the commercial standard is the one most readily set up. Mr. Van Scoyoc spoke of the cost of different types of highways, and common factors of cost in different types. He also gave specific examples of roads of different widths in township, county and suburban road construction and the proportion of cost to be borne by the province, county, city, or municipality. Also a few words on depreciation and maintenance of different types of roads. Mr. Van Scoyoc's paper will be printed in full in an early issue of the Contract Record.

The Importance of Road Maintenance

By Major J. M. Sheppard*

THE problem of maintaining the 42,000 miles of highways in the Province of Ontario will for all time to come, tax the energy and resources of the Road Engineer and call for an increasing and continuous expenditure.

When we realize that from one and a half to two millions of dollars in cash is expended annually by the Townships, and that an equal amount or more is worked out in a more or less useful way by Statute Labor, we begin to realize that it is time that a more practical and intelligent system of Road Maintenance should be inaugurated. Present conditions which are bound to increase and become exacting, demand something more efficient than Statute Labor, or the haphazard work that has tided us over in the past.

In addition to the large sum above mentioned, there has been expended since 1902 approximately $5,000,000 on different County Road Systems, the annual expenditure being now about $800,000. As it is the province of the County Road System to build roads that will be a stimulus and example to the Townships, so it must be the duty of the Counties to so maintain and care for the County Roads, that the townships whose roads are the feeders of the system, will build and maintain their roads in a like manner.

In most of the counties we are still in the constructive period and no doubt, further large sums will be expended on construction in the near future, but we must not forget in our enthusiasm for new roads, that the $5,000,000 already expended must be protected and the only way this can be accomplished is to carefully maintain the roads already built. To do this, it has been found in every case that some plan of permanent and continuous patrol must be organized.

Circumstances must, of course, determine what is necessary but the principle that someone is in charge of the road and responsible for its maintenance and that suitable material and tools are always available, so that repairs can be promptly made and damage and accidents avoided, must be kept in mind.

In some cases on the roads where the traffic is heavy and continuous, it is necessary to at once divide the highways into suitable divisions and employ permanent men to take charge. In other cases, men might be engaged and paid for the time actually employed. No matter which plan may be adopted, something must be done to preserve the original condition of the roads, following construction. The general public have too much interest and the taxpayers too much money invested to allow the roads to get into such a condition that they would have to be rebuilt in a few years.

A few of the main features of Highway Maintenance are noted as follows:

Drainage

As drainage is the first principle of construction, so it is the first to consider in maintenance. All side ditches culverts and outlets should be kept free from obstructions at all times, ice and snow removed when needed, and if possible underdrains laid where the road seems to have a tendency to heave; outside the metal or gravel kept smooth and shoulders thrown outside the ditch or removed so the water can flow to the side ditches and not sink into the road.

Weeds, brush and other obstruction of that kind ought to be kept down; not alone is it against the law

* Road Superintendent, Welland County.

to allow noxious weeds to grow on the highways, but weeds, grass and other objectionable matter growing on the side of the road give it an untidy appearance and hold snow and water and prevent quick drying. Too many trees also keeps the road wet, a heavy row of trees especially on the south side prevents the sun drying out the road. An effort should be made to have part of them removed or have them well trimmed up.

Hills

Hills require constant attention; the crown must be kept higher than on level stretches, as the water will follow the wheel tracks and wash out ruts. Side slopes also require to be watched to prevent slides filling up the ditches and turning the water into the road bed.

Culverts

Culverts also need care to prevent floating material from obstructing the openings; brush leaves, grass, etc., form dams which prevent the water passing through freely. When freezing follows the pressure of the ice cracks or breaks the tile or side walls and damage follows, which a few minutes attention would have prevented.

Guard Rails

Another matter that often needs attention is the guard rails which protect approaches to bridges and other dangerous places. Nothing looks worse than old broken and out-of-line rails that have been allowed to get out of repair, not alone the neglected appearance but the danger to the municipalities from their liability in case of accident. We know from experience that every one that goes on the highway is insured and the only way the public can be protected is to have all bridges, culverts and other dangerous places fool proof.

Finally

We must provide for an ever-increasing and continuous-wearing traffic. Ten years ago, it was a curiosity to meet a motor car, now on many roads it is just as rare to meet a horse-drawn vehicle, except it be a team doing farm work. The radius of travel is increased four-fold, before the era of the motor car ten miles was considered quite a journey to go and return in an afternoon, now forty miles is only a little spin. A few years ago, a farmer passed along his team making 3 miles an hour drawing fifty bushels of wheat weighing 1½ tons. Now the motor truck rushes past carrying four or five tons at a speed of 15 miles an hour. All these changes may make for the business and pleasure of the community, but they provide many problems for the future Road Builder.

Report of Committees

The committee on resolutions reported the following and recommended their adoption:—

1. That the Minister of Highways be requested to consider the advisability of making provision for supplying road building material at a minimum of cost.—Carried.

2. That we approve of the action of the Legislature in increasing their contribution towards the construction of county roads and by making provision for maintenance and express the hope that additional assistance will be granted when the provincial revenues warrant it.—Carried.

3. That we approve of the Bill to regulate the load of vehicles operated on highways, with the addition of a clause, authorizing municipalities to place notices on bridges already constructed specifying the load that they will carry, and that this notice be operative to protect municipalities for ten years or until a bridge is strengthened to carry the weight specified in the Bill.—Carried.

4. That the Highways department be requested to consider the advisability of supplying standard bridges to counties working under the Highway Improvement Act.—Lost.

5. That the section of the Municipal Act providing for the approval of County Bridge plans by the Provincial Highways department be extended to include the plans of bridges of 25 ft. or over in townships.—Carried.

6. That a uniform system of accounting for highway improvement should be considered by the Department of Highways, so that information showing the comparative cost of highways in the various counties receiving aid from the Province will be available.—Carried.

7. That the Good Roads Association arrange with the Department of Highways for a campaign of education in all countries that have not adopted a country road system under the provisions.—Carried.

8. That the Minister of Highways be requested to complete the construction of sample roads in the counties that have not adopted a county road system.—Lost.

9.—That the executive of the Good Roads Association be requested to continue their efforts to obtain lower freight rates for all road building material used by municipalities: and other matters pertaining thereto.—Carried.

10. That the secretary of this association convey to Major T. L. Kennedy, past president who is now on the firing line in France, their pride and satisfaction in knowing that one so long associated with the Good Roads movement in Ontario, is now upholding the honor of his country in its day of trial and express our sincere hope that he may live to return to us in victory, and that we may again have the pleasure of his presence among us and his sympathy and advice in the cause he has so much at heart.—Carried.

11. The Minister of Highways be requested to consider the advisability of amending the Highway Improvement Act by providing for the assessment of lands adjoining and contiguous to county roads, for benefit derived from the construction of said roads.—Carried.

Mr. G. S. Henry brought in the treasurer's report, which was accepted.

New Officers

Mr. J. A. Sanderson, past president, chairman of the nominating committee, presented the following list of new officers which was accepted: Honorary Presidents, N. Vermilyea, Belleville, and J. A. Sanderson, Oxford station; Pres. S. L. Squire, Watford; First Vice-President, C. R. Wheelock, Orangeville; Second Vice-President, J. J. Parsons, Haldimand; Secretary-Treasurer, George S. Henry, M.P.P.; Directors; W. H. Pugsley, York; Major Kennedy, Peel; L. E. Allen, Hastings; F. A. Senecal, Prescott; David Clow, Leeds, and K. W. McKay, St. Thomas.

Mr. A. T. Laing, secretary of the School of Science, Toronto, spoke of the road-builder as being almost as great a factor in the building of the Empire as the soldier in the trenches. Mr. Laing also spoke on the system of accounting in the counties under the Highway Improvement Act, and looks to see the time when people will see the advantages of a Good Roads system over and above the financial considerations.

Mr. George Hogarth, chief engineer of Highways, commented on the enthusiasm and interest shown in the convention, and extended an invitation from the Highways Department to the delegates present to consult them on any matters whatsoever in regard to highway improvement, at any time.

Major Kennedy, Past President of the Ontario Good Roads Association, who is now somewhere in Belgium, in a letter to the Secretary, Mr. Geo. S. Henry, M. P. P., described some of the roads over which he has passed on the way to the firing line.

The Raymond Concrete Pile Company, Limited, have been awarded the contract for the foundations and new additions to the Belgo-Canadian Pulp and Paper Company, Limited, plant at Shawinigan Falls, P. Q.

Aggregates for Concrete Roads

Important advances made in the knowledge of concrete aggregate which compose 80% of material in a concrete road—Life of concrete roads depends on the durability, grading, cleanness and chemical composition of the aggregates

By D. A. Abrams*

A permanent road must be designed and built to withstand three different destructive agencies; namely, traffic, weather, and structural stresses. All of these agencies must be adequately provided for. It is generally impossible to distinguish between the effects of traffic and weather; the combined effect of these two agencies requires the most careful consideration on the part of the road builder. Assuming that weather resistance and structural stresses have been properly considered in the selection of the type of road to be built, and in the design and methods of construction to be used, the total effect of all other desirable qualities of a permanent road may be expressed as its wearing resistance.

The wearing resistance of a concrete road subjected to given conditions of traffic and weather will depend upon the following factors, named in the order in which they are encountered: The properties of the concrete materials; proportions and consistency of mix; thoroughness of mixing; method of placing; surface finish; conditions of seasoning; and age of the concrete.

The wearing surface of a concrete road is subjected to a most severe usage. The aggregates constitute 75 to 85 per cent. of the material in a concrete road; hence the resistance to weather and traffic, and the final integrity of the structure, depend largely on the properties of the aggregates. Aggregates of the highest quality are essential. It is the function of this committee to report on the present state of our knowledge of concrete aggregates.

Properties of Concrete Aggregates

Important advances have been made in our knowledge of concrete aggregates and in the practices governing the selection and use of these materials since the adjournment of the First National Conference on Concrete Road Building. The carefully compiled specifications for aggregates formulated by that Conference and other bodies have been widely adopted and used with results which have been most beneficial. Greater care in the selecting and testing of aggregates has been a characteristic feature of recent practice in concrete road construction.

Experience has shown that, other factors being equal, the life of a concrete road depends on the following qualities of the aggregates:

Durability of particles. (Toughness, strength, hardness, brittleness, density, resistance to weather, impact, abrasion, etc.)

Grading. (Size and shape of particles, amount of voids, etc.)

Cleanness. (Amount and character of impurities.)

Miscellaneous properties. (Chemical and mineralogical composition, structure, etc.)

These properties are named in the order of their importance for usual conditions.

All tests of concrete aggregates are made for the purpose of classifying the materials with reference to one or more of these qualities. Since wearing resistance is an important property of concrete for road building, we are principally interested in those qualities of aggregates which combine to produce a concrete of high resistance to wear.

Testing Concrete Aggregates

All tests of structural materials are made for the purpose of enabling the constructor to learn in advance of use whether the material is suitable for the purpose and to determine the relative utility of different available materials. The knowledge gained from the experimental studies of aggregates has not kept pace with the demands of construction. Most of our knowledge of the requirements for aggregates for use in concrete roads has been derived from observation of the behavior of the materials in service.

Due largely to the recognition of the necessity for careful scrutiny of the materials which are proposed for use in concrete roads, a wide-spread interest has arisen during the past few months in the study of aggregates and the tests which may be expected to indicate their suitability for this and other service. Aggregate testing as practised at the present time is of recent origin, hence standard methods for conducting many of the tests have not been developed. Several of the leading engineering societies now have technical committees which are actively engaged in studying these problems. The testing of concrete aggregates is receiving more attention at the present time than ever before. It seems probable that these materials are now the subject of a larger number of experimental studies than any other group of engineering materials. Many of the materials testing laboratories are carrying out researches which will prove of the utmost value in arriving at a rational basis for proper specification requirements and tests.

It may be expected that long experience would indicate the relative merits of different materials and methods of constructing concrete roads. It is the function of careful tests and experimental researches to replace evolution and accomplish the desired results without the costly errors and delays which generally result, if the lessons of experience in service are to be our only guide. The tests of service will, of course, continue to be the court of last resort in determining the fitness of a material and the value of methods of construction, as well as to furnish a guide to proper laboratory tests.

Aggregate Tests

Tests of concrete aggregates may be made on the materials as delivered for use, or on mortars and concretes made from the materials.

Concrete is a manufactured product which results from mixing cement, water and suitable inert materials in the proper proportions and allowing the mass to season under favorable conditions. Recent advances in materials testing show the advantages of testing the finished product or the completed structure, rather than attempting to determine the quality of the pro-

*Chairman of Committee on Concrete Aggregates, before National Conference on Concrete Road Building, Chicago.

duct solely from information gained by a study of the component materials.

The wearing resistance of concrete is its most important characteristic for use in roads. Wear on a road surface is due to the combined action of stresses such as impact, abrasion, crushing, etc. Experience shows that concrete which will withstand street traffic will give a good account of itself in other respects. These considerations suggest a wear test of concrete as the most direct method for studying the relative merits of different materials and methods. Experimental work of this kind is in progress in several laboratories.

The Talbot-Jones Rattler, which was originally designed for tests of paving brick, has been used for exposing the concrete surface to the tumbling action of a heavy charge of iron shot or blocks. This test is the most promising which has come to the attention of the committee. The Deval Abrasion Testing Machine has also been used for tests on small mortar speciments. These methods of testing have not been studied sufficiently to fully establish standard methods and to indicate the exact relation between the indications of the tests and the behavior of similar concrete in service. The data now available on wear tests of concrete do not justify the attempt to formulate specification requirements for aggregates on the basis of such tests.

In the absence of a satisfactory wear test of concrete, we must continue to depend upon the tests of materials and concrete which have been shown to be significant in furnishing information on the quality of the aggregates.

On account of the great economies which result from utilizing materials that are readily available, and the absence of well-developed sources of supply in many localities, it is of prime importance that all aggregate materials for concrete roads be tested before use. All engineers of wide experience in concrete road building agree as to the importance of careful selection of aggregates.

In the following discussion only the more important tests are mentioned. A complete discussion is not attempted.

Under the heading "Durability," a number of the fundamental physical properties of aggregates have been grouped. It is difficult to discriminate between the effect of toughness, strength, hardness, brittleness, and resistance to weather, impact, abrasion, etc., in aggregates. It has not generally been considered necessary to make tests for the purpose of determining the effect of each of these properties. However, even though no tests are made, we must consciously or unconsciously weigh and pass judgment on all these factors before we can reach a conclusion as to the suitability of a given aggregate for use in concrete roads.

No satisfactory method of measuring the hardness of an aggregate is available. The exact influence of different degrees of hardness of the aggregates on the wearing resistance of concrete has not been determined. However, it would seem that the hardness of the aggregate should be well in excess of that of the cement itself after it has thoroughly set and seasoned, to the end that the impact and abrasion of traffic may be fully resisted. Uniformity in the qualities of an aggregate is of the utmost importance.

A direct determination of the compressive strength of an aggregate is seldom necessary, since the ultimate value of a material for concrete road building generally depends on other factors.

Certain tests for determining the toughness, abrasive resistance, etc., of crushed rocks have been used. These tests were introduced in this country by the United States Office of Public Roads. They have heretofore been carried out with particular reference to determining the suitability of rocks for use in macadam road construction. It is not clear now just what relation the evidence of these tests has to the suitability of a crushed rock for use as a concrete aggregate. Some of the tests which generally have been made cannot readily be applied to material of the size used for aggregates; none of them is applicable to natural sands and gravels. Modified forms of the standard abrasion test with the Deval Abrasion Testing Machine have been used by some engineers as a basis for specification requirements for concrete aggregates. In these tests charges of cast iron or steel shot have been placed in the test chamber with the aggregate sample. The proportion of material reduced below a given size is taken as a measure of the abrasive resistance of the aggregate. This form of test deserves further study. There is a great need for a simple standard test which will serve to distinguish between aggregates which are too soft or too brittle for use in concrete roads, and those which may be expected to give satisfactory results.

Weather resistance is an important property of materials which are to be used in the wearing surface of concrete roads. A laboratory test which will furnish a reliable guide to the weather resistance of rocks under different climatic conditions has not been discovered, although many tests have been proposed and used. Alternate freezing and thawing, acids and disrupting agencies represent the most commonly used tests for this purpose.

The appearance of natural sands and gravels and a consideration of their origin and geological history will frequently furnish an indication of their probable resistance to weather. The examination of portions of the same stratum which has been exposed to the weather for several years will generally furnish a satisfactory criterion of the weather resistance of a crushed rock.

Grading

The division of aggregates into fine and coarse is an arbitrary one. The distinction arose, no doubt, from the practice of securing the fine and coarse materials from different sources, and has been preserved largely for convenience in proportioning. It is almost universally customary to consider particles smaller than ¼ inch as fine aggregate and larger material as coarse aggregate.

Experience in the use and testing of concrete has shown that with a given proportion of cement, wide variation in the quality of the concrete results from differences in the grading of the aggregates.

A study of tests of sands and sand mortars indicates that the grading of the material, or the relative proportions of the particles of different sizes, is one of the most important factors which influence the mortar-making qualities of natural sands. All tests emphasize the advantage of using sands in which the coarse particles predominate and the fine are reduced to a minimum. A coarse, well-graded sand gives low voids, hence correspondingly high strength and improved wearing qualities. The so-called straight-line grading of sand conforms closely to that giving the highest strength in mortar tests. However, a certain degree of "workability" is essential; hence a larger proportion of fine sand than that indicated by the straight-line grading is generally desirable and is nearly always found in natural sands.

It seems probable that a more thorough study of the effect of grading of sands will demonstrate economies which may be effected by more accurate grading, and make it desirable to specify the required grading within narrower limits than is now customary. It is frequently found that a high-grade, fine aggregate can be produced by combining in the proper proportions two lots of material, neither of which is satisfactory for concrete roads if used alone. The mixing of fine sand with a coarse sand or screenings from crushed rock of good quality is sometimes an economical procedure.

It seems probable that the grading of coarse aggregates exerts an important influence, although the relative variation in grading is generally much less than in natural sands.

The earlier builders of concrete roads used coarse aggregate graded from about ¼ to 1 or 1¼ inches. It has long been recognized that concrete of greater density and strength can be produced by using coarser material. A saving in the cost of crushing can be effected by using aggregates as coarse as the nature of the work will permit. With the richer mixes that are now common in concrete road construction no difficulty is encountered in placing and finishing roads with aggregates graded up to 2 inches. It is believed that this size of material will produce a superior concrete for use in a one-course road. In two-course construction or where required by local conditions of supply, finer material may be used.

In certain instances it may be desirable to consider fine aggregate as material graded up to ⅛ inch instead of ¼ inch. In this case corresponding changes must be made in the specification requirements for the grading of aggregates and in the proportions used. The use of fine aggregate graded up to ¼ inch is recommended.

Owing to the wide variations in practice in screening coarse aggregates, it does not seem feasible to specify the sizes to be required, within too narrow limits.

There is great need for a standardization of sieve sizes and of the methods of conducting sieve tests both of fine and coarse aggregates.

The voids in aggregates are largely a function of the shape and grading of the particles. Low voids should be secured, since the strength and "workability" of the concrete will thus be greatly improved. A well-graded natural sand will show voids as low as 28 per cent.; in a poorly graded sand the value may be as high as 38 per cent. The voids in crushed stone frequently run to 50 per cent.

Cleanness

The impurities in aggregates generally consist of clay or loam. The presence of a small percentage of clay in a loose, finely divided condition is not usually found to be harmful. Clay which coats the particles is likely to prove injurious. A large percentage of clay in sands or gravels suggests the presence of clay pebbles. The presence of vegetable loam or other organic materials always has a deleterious effect. Mica in sand reduces the strength of the mortar. The possibility of the presence of other impurities should not be disregarded.

The term "silt" is used to designate all foreign material which may be present in an aggregate in the form of a coating on the grains or in a finely divided state, or which is of a soft or soluble nature. It is in tests of natural sands that a study of the silt is most important. Various methods of determining the amount and nature of the silt are in use.

Washing a given weight of sand in a glass percolator with running water under a constant head until the wash water becomes clear, and determining the amount of silt on the basis of the loss of weight, seems to be the most accurate and scientific method for laboratory use. For a discussion of another method, see Appendix A, on "Field Inspection of Aggregates." A chemical analysis of the silt frequently indicates the presence of injurious materials. The strength test of mortars and concretes generally furnishes a safe criterion of the effect of such impurities as are contained in the silt.

Miscellaneous Tests

The exact bearing of the chemical and mineralogical composition of an aggregate on its suitability for use in concrete roads has not been definitely established. In so far as variation in these properties affects the toughness, resistance to weather, wear, etc., they will influence the final value of the material. The form of fracture, and the nature of the surface of the particles, have an important bearing on the road-making quality of aggregates.

Tests of Mortars and Concretes

A discussion of the properties of concrete aggregates must of necessity deal largely with tests of mortars and concretes. A wear test of concrete, standardized with reference to the behavior of concrete in service, would furnish the most direct indication of the value of different aggregates for concrete road construction. Such a test would be of assistance in studying the effect of other variables such as the proportioning, mixing, and seasoning of the concrete.

A suitable strength test of a mortar or concrete made up from cement and the aggregates in question is without doubt the most reliable single determination which can be made in view of our present knowledge. This test gives information as to whether or not the aggregate affects the setting and hardening of the cement—a consideration of prime importance. It also indicates what may be expected from the standpoint of strength. If the form of test specimen, proportions, method of mixing, seasoning, etc., are standardized or are made to approximate those used in the work, an excellent indication can be secured of the probable strength of the concrete in the structure. It is apparent that tests of concrete furnish the best criterion of the concrete-making quality of either a fine or a coarse aggregate.

(Continued in next issue.)

Damage to Sooke Lake Waterworks

Twelve lengths of pipe were swept away and considerable water wasted owing to a break in the concrete flow line of the Sooke Lake waterworks system Jan. 22. This is the first accident which has occurred to the line. It was caused by a landslide. The damage is slight, it is reported, and until repairs can be made a temporary wooden trestle bearing a wooden flume will be used. The water stored in the Humpback reservoir is reported to be more than sufficient to supply the city while repairs are being made.

Developing the Export Trade of the Dominion

A special luncheon of the Canadian Manufacturers' Association was held on February 23rd at which the members were given an opportunity of hearing an address by Mr. F. C. Armstrong, European manager of the Export Association of Canada, Limited. Mr. Armstrong is on a brief visit to Canada, after making a careful study of the general business situation in England and France. While abroad he had exceptional opportunities for obtaining reliable information regarding the fiscal policies likely to be adopted by the allies in the near future. Mr. Armstrong said that he had gone to England to look over the situation there and on the continent, in behalf of the Export Association of Canada. He had now returned to report upon the position as he found it, and to consult with the directors and shareholders of the Association as to future steps.

The speaker stated that the subject of export trade was of the most vital importance to every Canadian. Next to the winning of the war the most important thing for Canada and for all the allies was to organize their manufacturing industries, transportation facilities, etc., so thoroughly that after the war the prosperity of the country would go on without interruption. When one spoke of "after the war" there had formerly been a great deal of misunderstanding as to just what war meant. During his visit to England and France he had realized that a great unanimity of opinion was developing as to what this term involved. The people of the allied countries had come to realize that they could not be satisfied with winning the war, but must rid the world of German aggression after defeating Germany's army in the field. If they allowed Germany, after the war, to build up her commerce and wealth, they would be giving her power once more to forge another weapon with which to renew her scourge upon civilization. Therefore it had become a matter of the salvation of humanity that Germany should not again be entrusted with the power to repeat the damage which she had been inflicting during the present war.

It was necessary, first of all, to crystallize public sentiment into some concrete and definite understanding of the method by which they could put it beyond the power of any individual to buy German goods, or, if he bought them, to make the price so high that the goods would no longer be attractive. The ordinary machinery for accomplishing such a result was that of tariffs. Mr. Armstrong had spoken with many representatives of both political parties in Great Britain and had become convinced that all were now a unit upon the subject of dealing with the tariff question on national and economic lines. Prominent Liberals had told him that there would be no resumption of the tariff fight. The free trade and conscription fights in Great Britain had gone into the melting pot. England would deal in future with the tariff problem from an entirely new angle, so that the way would be clear for working out a plan for consolidating and strengthening the whole Empire.

The British Government and nearly every important commercial association in Great Britain had taken the matter actively in hand and were calling for some form of preferential trade arrangements which would be effective along these lines. Sir Richard Musgrave, secretary of the London Chamber of Commerce, had put the matter in a very definite form, saying that what they had in view was, first of all, to make arrangements for looking after the interests of the Empire, then to do all they could to promote the interests of the allies, then to treat with neutrals as they had deserved, and finally to deal with the enemy and to take the necessary steps to exclude his trade from allied countries. Invitations had been sent out, Mr. Armstrong said, for a meeting on June 4th, of the Imperial Chamber of Commerce, to be held in London, the chief object of which would be to get the best business opinions from the different portions of the Empire to aid in working out the commercial problems which would develop after the war. First of all, he believed, there would be a trade preference given within the British Empire,

It was important, therefore, to perfect their representation in all the countries which make up the Empire, in Australia, New Zealand, South Africa, the Crown Colonies, India, etc. The Export Association of Canada had already been able to make arrangements for representatives in New Zealand and Australia, both of which organizations were working extremely satisfactorily, except for the difficulty in securing transportation. These representatives would no doubt become distributing machinery of great value. In England Mr. Armstrong had been able to conclude arrangements for promoting Canada's trade with the Crown Colonies. He had even been able to secure orders for many thousands of dollars worth of material, which, in most cases, unfortunately, we could not supply because we were so heavily engaged in the production of war order materials. Canada, however, could count upon a very large field for her manufactured goods in these colonies in the future.

In regard to India and the east it had appeared to him to be inadvisable to open up connections there at present when they were unable to furnish either the goods or the transportation. The promotion of trade in these countries might be left in abeyance for the time being.

In South Africa they were being pressed by the Trade Commissioner, Mr. Egan, to extend their organization and to help in building up Canada's trade with that country.

Perhaps the most difficult country of all to deal with was Great Britain, especially under the present restrictions in regard to transportation. The recent statement by Mr. Lloyd George that the Government of Great Britain had made a mistake in not taking complete control of shipping at the beginning of the war was of great importance. Mr Armstrong believes that if the Government should take control of shipping, Canada would really be benefited thereby because, when tonnage is scarce it is inadvisable to tie up shipping in carrying goods from very distant countries such as Australia and the Argentine, when the necessary materials can be had from countries such as those of North America which are so much nearer Great Britain.

At the beginning of the war Great Britain had lost considerable confidence in the ability of Canada to supply war materials. In those days the manufacturers of Canada had not been organized, nor had they been able to study all the important aspects of the problem.

Mr. Armstrong drew attention to Germany's former strong position in regard to international trade. After the war, many countries would be urgently in need of articles which formerly were only made in Germany. The allied countries could only complete Germany's economic defeat by supplying these materials. Russia had been buying 300 million dollars worth of goods from Germany annually, in fact over fifty per cent. of the manufactured goods she imported. She could not produce these goods herself. As soon as the war was over she would have to get them. She would not be able to buy them from France or Belgium, because all of Belgium and the finest manufacturing districts of France had been devastated by Germany. She would have to turn to Great Britain, which country, being fully occupied, would only be able to take care of a portion of the demand. So Russia would have to come across the Atlantic. She would come to Canada, beyond any doubt. But she would not come to Canada to anything like the possible maximum ex tent unless we went to Russia first, and showed her our ability to furnish such materials as she required. We must therefore study the markets of Russia and organize our production, distribution and finance, otherwise this business would go to the United States, which was already organizing for the purpose in the most thorough manner possible.

Mr. R. J. Young, Joint Manager of the Export Association of Canada, Limited, also spoke briefly, emphasizing what Mr. Armstrong had said regarding the importance of organization and stating that he intended to call upon as many Canadian manufacturers as possible, chiefly those directly interested in the export situation, so as to urge upon them the necessity for joining the Association. Some time in June or September they intended to hold a Canadian National Export Trade Convention which would bring together the carriers, the financiers, the manufacturers and every other national interest which was a factor in the building up of export trade.

Personal

Mr. M. J. Costello, of Seattle, traffic manager on the Pacific division of the Great Northern Railway, stated recently that the railway would proceed this year to construct more concrete snow sheds in the Cascades.

Mr. W. W. Pearse, city architect of Toronto, favors a new type of revolving door, which, upon cross pressure being applied, collapses, thus creating two clear openings with the collapsed door in the centre. The old type of revolving door is not condemned by Mr. Pearse, but he points out that in case of panic it would certainly be a source of danger.

Mr. Christopher J. Yorath, civic manager of Saskatoon, Sask., delivered an interesting address before the Ottawa Board of Trade on February 18th, his theme being Civic Government. Mr. Yorath, who is an expert on this subject, outlined the various systems of conducting municipal administration. The impression his remarks made on his hearers was evidenced by the discussion which followed.

Mr. A. F. Macallum, city engineer of Hamilton, Ont., has been elected president of the Society of Engineers of North America. He also received another tribute to his abilities recently in being asked by the Canadian Fire Underwriters' Association to act as their arbitrator in connection with hydraulic disputes in several Canadian cities. Stress of local business made it necessary for Mr. Macallum to decline this offer, however.

Messrs. Forrest & Lightfoot, consulting engineers and contractors, have opened an office in Morin Block, Mountain Hill, Quebec. Both of these gentlement have had much experience in their work. Mr. Lightfoot has been connected with the contracting business for eighteen years. He was an engineer on the staff in connection with the construction of the immense Transcona shops at Ottawa. Mr. Forrest is well and favorably known in Quebec. He was but recently Government engineer in charge of the construction of the St. Malo shops in Quebec. He has also been connected with railroad and building construction work, both in the United States and Canada.

Mainly Constructional

Rees & Hawken, builders, Toronto, have dissolved partnership.

The Eastern Machinery Company, Montreal, Que., have registered.

The Phoenix Building Company, Limited, Quebec, Que., have been granted a charter.

The Andrews Wire Works of Canada, Limited, Watford, Ont., suffered loss by fire recently.

MacIntyre Granite Quarries & Manufacturers, Limited, have been incorporated, headquarters in Winnipeg.

Phoenix Iron Works, Limited, is the name of a new Vancouver concern incorporated with a capital of $10,000.

Thomas Tomlinson, proprietor of the iron foundry business of Tomlinson & Son, Toronto, died on February 22.

The Western Ontario Clay Workers held their nineteenth annual convention in the Builders' Exchange, London, Ont., on February 23 and 24.

It is announced that, as the entire staff of the firm of Chadwick & Beckett, architects, Toronto, are now on active service or making munitions, the office has been closed.

Building permits issued by the city of Chatham, Ont., in the month of January, 1916, totalled $9,500—an increase of $6,525 over January, 1915, when the value of the permits issued was $2,975.

The H. P. Peterson Construction Company, Limited, has been incorporated, and will carry on a general contracting and engineering business in Vancouver, B. C. The capital stock of the company is $10,000.

A fire causing a loss estimated at between fifty and one hundred thousand dollars occurred on the 10th ult. at the premises of the Record Foundry and Machine Company, Moncton, N. B. The loss is covered by insurance.

The partnership which existed between John Hastie and McPherson & Fullerton Bros., as contractors in the city of Victoria under the style of the British Columbia Construction and Engineering Company, has been dissolved by mutual consent. Mr. John Hastie will continue the business.

Hayden, Stone & Company, of Boston, have organized under Massachusetts laws the Cuban Portland Cement Company, to manufacture and sell Portland cement in Cuba. The new company will have an authorized capital of 200,000 shares, par $10, of which 100,000 are to be sold by the company at $15 a share.

Plans are being prepared for a big steel bridge over the Peace River at Peace River Crossing, Alberta. It will include a traffic deck, and the total cost of construction will be about three-quarters of a million dollars. The building of this bridge will enable the line of the Central Canada Railway Company to be continued westward.

The annual meeting of the Manitoba Good Roads Association was held in the board room of the Industrial Bureau, Winnipeg, on February 14. The president, Mr. S. R. Henderson, submitted his sixth annual report, showing the excellent work accomplished by the association during the year in all matters pertaining to better roads.

The annual convention of the Provincial Builders' and Supply Association was held on February 22 and 23 in the rooms of the Builders' Exchange, Hamilton, Ont. There was a good attendance. Mr. George Gander, of Toronto, president of the association, presided. On the evening of February 22 the delegates were entertained at a banquet held in the Wentworth Arms.

The Princess Theatre, Toronto, is to be rebuilt. If arrangements can be made, the work will be started at once, in the hope that the theatre will be ready for the season commencing in September. The seating capacity will be increased from 1,850 to 2,200, and the building will be made twenty feet wider. The work is expected to cost in the neighborhood of $200,000.

W. A. McLean, Deputy Minister of Public Works for Ontario, reports that in accordance with the provisions attending increased Government grants to municipalities undertaking schemes of roadway construction, plans for an improved system of roadways are being prepared by the following counties:—Brant, Lambton, Kent, Victoria, Elgin, Prescott, Dundas and Stormont and Glengarry.

The expenditure during the past fiscal year on the Quebec Bridge was $2,816,305, paid out of capital, making the total capital expenditure on the reconstruction of the bridge $7,764,393. The total expenditure by the railway department up to the end of the year in connection with this bridge is given as $8,198,748, irrespective of the subsidy of $374,253, paid by the Quebec Bridge Company, and of the sum of $6,975,266, paid for the guaranteed bonds of that company.

"Better Roads for Alberta," was the subject of an address given by the president, Mr. J. H. Lamb, at the recent convention of the Alberta Association of Local Improvements, held in Edmonton. Mr. Lamb said that the Government had spent over six million dollars since 1905 on roads and bridges in the province, but a great many miles of roads were to-day in the ditch. He urged the maintenance of the roads, and the construction of permanent roads throughout the province—particularly on behalf of the farmers, who, he said, did not receive benefits commensurate with the vast sums expended on roads.

Messrs. Pearson and ~~Martin~~ MARCHAND, the architects who were asked by the Government to examine the condition of the Ottawa Parliament Building after the fire, report that with the exception of the central interior and the rear walls the structure itself can be repaired without entirely rebuilding. Most of the walls are still intact, and what is left of the building represent a value in labor and material of approximately two million dollars, or considerably over half of the original cost. A tentative ground plan of the main Parliament Buildings has been prepared, and it is probable that an early start will be made on the work of reconstruction.

Saskatoon is in a fair way for adding another to its industries, in the form of reinforced concrete products, which is likely to commence operations this spring. Mr. A. C. McEown has an incorporation with extensive powers known as "Sand and Gravel Deposits, Limited," the object of which is to manufacture concrete chimneys, fence posts, window sills, ornamental work, etc. Mr. McEown is now showing a reinforced concrete block for chimneys, which will be made in different sizes. This chimney, it is contended, will not sweat or drip, and will give perfect ventilation. When built, the chimney has a double wall with an air space between, and is reinforced with wire running through each wall and the connecting walls.

The opening proceedings of the annual convention of the International Association of Master House Painters and Decorators of the United States and Canada, which was held in Cincinnati last month, were delayed for thirty minutes because no British flag bearing the coat-of-arms of Canada was displayed in the decorative scheme of the hall where the meeting was held. There were two American flags draped above the speaker's stand, and between them was the United States shield, with an insert of the Canadian coat-of-arms. Many Canadians are members of the Association, and those present at the convention refused to consider any business until a British flag bearing the Canadian shield was included in the display. A committee appointed for the purpose succeeded in finding such a flag after spending half an hour in visiting many stores.

Mr. James H. McKechnie, president of the Canadian Consolidated Rubber Company, Limited, and also president of the Canadian Consolidated Felt Company, Limited, passed away on February 8, following a brief illness of ten days. In 1877 Mr. McKechnie commenced the manufacture of waterproof clothing, and in 1883, in company with the late S. H. C. Miner and others, organized the Granby Rubber Company, of which he became general manager. When that company was amalgamated with the Canadian Consolidated company Mr. McKechnie became vice-president of the latter, and in April 1915 was elected president. His sterling qualities and fine character exerted an influence for the betterment, not only of business conditions, but of the community in which he lived. That his death is sincerely regretted is evidenced by many messages of sympathy that have been received from all parts of Canada and the United States.

The men who have been engaged in making charts of the different channels in the Fort William, Ont., harbor will finish their task shortly, according to Mr. Craig, the local government engineer. Each winter, after ice has formed upon the water, a chart is made of the channels, showing the depths, widths, and other particulars, so that the government is able to strike an estimate of the amount of money required to carry on the harbor work during the months of navigation. It is too early yet to get any line on just how much work will be done in the harbor this year, but it will likely be of considerable quantity. Some of the old channels have to be deepened, and it is probable that efforts will be made to complete the turning basin in the Kaministiquia River above the Grand Trunk Pacific railway bridge. Between ten and fifteen acres of land remains to be dredged out. Another undertaking which most likely will be completed this summer is the new breakwater at the Mission. Part of this huge concrete wall was seriously damaged last fall in a big snow storm, when it was cracked and part of it shifted.

The special committee appointed by the Quebec Health Committee to make a test of the city's water supply and to confer with experts on the best means of purifying it have recommended the adoption of a sterilizing system of chlorination as the most practical for the time being, in view of the vast expenditure which a filter system would entail. The latter system, it was pointed out, would cost about $300,000, besides an additional $35,000 a year for upkeep. On the invitation of the special committee Mr. George A. Johnson, expert sanitary engineer, of New York, has been in Quebec making a thorough inspection of the water-works. In his report Mr. Johnson says that the water shows the presence of bacteria of sewage origin, and strongly recommends the immediate construction of a filtration plant as the only means of rendering the water pure. He points out that sterilization by chlorination will not do more than kill a large proportion of the bacteria, but advises the installation of such a plant pending the construction of a filtration plant. When the filtration plant has been built and put in operation, says Mr. Johnson, the chlorination plant can be made a part of it, and be continued as a desirable adjunct to the filtration process of purification.

New Books

The Colorado Industrial Plan—by John D. Rockefeller, Jr. This booklet contains a complete copy of the Plan of Employees' Representation—or "Industrial Constitution"—and the agreement between the company and its employees adopted at the coal and iron mines of the Colorado Fuel and Iron Company. In order that the scope and purpose of the plan may be more clearly understood, there are also included an article entitled "Labor and Capital—Partners," reprinted from the Atlantic Monthly for January, 1916, and two addresses delivered by John D. Rockefeller, Jr., while in Colorado in October, 1915.

Altitude in Canada—by James White, F.R.S.C., F.R.G.S., assistant to chairman and deputy head of the Commission of Conservation of Canada. The report is accompanied by a number of valuable maps, showing the profiles and altitudes along the transcontinental lines, C. N. R., C. P. R., and G. T. P. An interesting map also is that showing the high and low levels since 1866 of the four Great Lakes.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Anderdon Township, Ont.
The Township Council contemplate a large amount of drainage this season. Clerk, A. C. Mailloux, Amherstburg.

Brant County, Ont.
The County Council. in conjunction with the Ontario Highways Board, are considering the establishment of a good roads system. Engineers, Jackson & Company, Temple Building, Brantford.

Brantford, Ont.
G. A. Ward, Chairman of the Board of Works, will receive tenders until noon, March 13th, on the supply of vitrified sewer pipe, sizes 6 to 24-inch. Specifications at office of the Engineer, T. H. Jones.

Drummondville, Que.
The Town Clerk, W. A. Moisan, will receive tenders until 7 p. m., March 15th. for the construction of a pumping station and mechanical gravity filters. Plans and specifications at office of the Clerk and of the Consulting Engineers, M. M. Ouimet & Lesage. 76 St. Gabriel Street, Montreal.

Dudswell, Que.
The Municipality propose to spend $4,000 during the year on the construction of roads. Secretary, H. Cunningham.

Humberstone, Ont.
The Village Council propose to spend $3,000 on roads and sidewalks. Clerk, John J. Wichman.

Leeds & Lansdowne Township, Ont.
The expenditure of $8,000 on roads is being considered by the Township Council. Clerk. J. D. W. Darling. Lansdowne, Ont.

Lindsay, Ont.
The Town Council are considering the expenditure of $2,500 on sewers, $2,500 on sidewalks and $2,500 on waterworks. Clerk, D. Ray.

London, Ont.
The City Council contemplate the laying of asphaltic concrete pavement on Waterloo Street and Carfrae Crescent, at an approximate cost of $23,200. Clerk, S. Baker.

The City Council propose to purchase an asphalt plant and to submit tenders on all paving required during the year. Engineer, H. A. Brazier.

Moncton, N. B.
The City Council contemplate the expenditure of $60,000 on sewers and $50,000 on pavements. Clerk. J. S. Magee. Engineer, J. Edington.

Napanee. Ont.
Work by day labor will start in the spring on the construction of cement walks for the Town Council. Clerk, W. A. Grange. Estimated cost, $5,000.

Niagara Falls, Ont.
Tenders will be received until noon, March 8th, by B. Carr, Secretary to the City Council, for excavation and backfilling of trenches for watermains.

Pelee Island, Ont.
The Township Council will shortly call for tenders on a quantity of ditching and rock blasting for Big Marsh improvements. Particulars from C. Parsons, Pelee Island.

Port Credit, Ont.
The Village Council have passed a bylaw providing for the construction of a number of sidewalks. Clerk, F. W| Ott.

Preston, Ont.
The Town Council propose to spend $25,000 on pavements and $5,000 on sewers and sidewalks. Clerk, H. C. Edgar.

Quebec, Que.
The City Council contemplate purchasing an asphalt plant at an estimated cost of $12,000 and the installation of a filtration plant. Engineer, W. D. Baillairge.

Regina, Sask.
Tenders will be received until noon, April 1st, by the Division Engineer, T. C. McNabb, Moose Jaw, for paving approaches to the freight sheds. Plans, etc., with the Division Engineer, with J. G. Sullivan, Chief Engineer, Winnipeg, M. McKenzie, Resident Engineer, Regina, C. S. Moss, Resident Engineer, Moose Jaw, and E. A. Kelly, Resident Engineer, Saskatoon.

St. Francois, Que.
The expenditure of $5,000 on sidewalks is proposed by the Municipal Council. Clerk, J. D. Jutras.

Toronto, Ont.
Commissioner of Works R. C. Harris has recommended the construction of an asphalt pavement on Pacific Avenue at an estimated cost of 47,800 and a brick block pavement on Lansdowne Avenue at an approximate cost of 5.821.

Truro, N. S.
The Town Council propose to construct about 1,300 yards of concrete sidewalks this season. Clerk, H. McDougall.

Valleyfield, Que.
The Town Council are about to start work on the laying of a macadam pavement, estimated to cost $5,000 and the construction of cement walks at an approximate cost of $4,000. Engineer, Oscar Viau.

CONTRACTS AWARDED

Ottawa, Ont.
The City Council have let the contract for the supply of pipe required in the construction of the distribution system to the National Iron Works, Ltd., Cherry Street, Toronto.

Railroads, Bridges and Wharves

Esquimalt, B. C.
The sum of $200,000 for improvements to the dry dock is included in the estimates of the Department of Public Works, Ottawa. Secretary, R. C. Desrochers.

Marieville, Que.
The Town Council are considering the erection of a concrete bridge, estimated to cost $4,000. Clerk, J. E. Ostiguy.

North Vancouver, B. C.
The District Council have instructed Engineer A. M. West to prepare estimates of the cost of repairs to the wharves at Cove Cliff and Woodlands.

Toronto, Ont.
The Board of Control will receive tenders until March 14th for special track work, etc., for the Civic Railway. Plans at Room 12, City Hall.

Vancouver, B. C.
The Department of Public Works, Ottawa, have included in their estimates the sum of $350,000 for harbor improvements.

Victoria, B. C.
Provision has been made in the estimates of the Department of Public Works, Ottawa. for improvements to the harbor. Approximate cost, $100,000.

Warwick Township, Ont.
The Township Council propose to spend about $6,000 on bridges throughout the Municipality. Clerk, N. Herbert, Watford, Ont.

CONTRACTS AWARDED

Victoria, B. C.
The Canadian Northern Railway Company, Toronto, have awarded the contract for the construction of a wooden bridge over Selkirk Water to S. Doe, 522 Sayward Building.

Public Buildings, Churches and Schools

Alberta Province.
The Department of Public Works, Ottawa, have made provision in their estimates for the erection of the following buildings:—

Grand Prairie, Immigration Hall, $3,000.
High River, Public Building, $20,000.
Macleod, Public Building, $25,000.
Medicine Hat, Immigration Hall, $20,000.
Red Deer, Public Building, $34,000.
Vegreville, Public Building, $25,000.
Vermillion, Public Building. $20,000.
Wainwright, Public Building, $20,000.

Bracebridge, Ont.
The School Board are considering the installation of lavatories at the schools. Estimated cost. $4,000.

Cayuga, Ont.
The Board of Education propose to build a new wing to the school. Brick construction. Secretary, E. B. Davis, Cayuga.

Davidson, Sask.
The erection of an office building is contemplated by D. S. Hutcheon.

Delia, Alta.
The erection of a school is contemplated by the Trustees of School District No. 3261. Estimated cost, $3,000.

Emerson, Man.
The School Board are considering the erection of an addition to the school.

Exeter, Ont.
Alterations to the Sunday School rooms of James Street Methodist Church are being considered. Estimated cost, $4,000.

Fitch Bay, Que.
The School Commissioners are having plans prepared for a school, estimated to cost $3.000. Secretary B. H. Rider.

Fort William, Ont.
It is intended to rebuild St. Luke's church, which was recently destroyed by fire. Pastor, Rev. Canon Burt, 213 Cameron Street.

Joliette, Que.
Tenders on the erection of a school will be called in about one month. Stone, brick and frame construction. Approximate cost, $20,000. Secretary to the School Commissioners, J. M. Mondor.

Masonville, Ont.
The erection of an addition to the school is being considered by the London Township Council. Secretary, Mary Grant, 110 Dundas Street, London.

New Dundee, Ont.
Work on the erection of a Town Hall will start shortly under the supervision of Charles Beckman. Frame construction.

North Ridge, Ont.
Plans are being prepared by J. C. Pennington, La Belle Building, Windsor, for a school to be built for the Public School Trustees. Concrete block and brick construction, concrete foundation, shingle roofing. Estimated cost, $5,000.

Stamford Township, Ont.
Tenders will be received until March 14th on the erection of a school for the Trustees of School Section No. 2. Plans at office of the Architect, J. U. Collins, 49 Benson Street, Niagara Falls. Red brick construction, stone foundation. Approximate cost. $6,000.

Stanstead, Que.
Loomis, Dakin Ltd., St. Gabriel Street, Sherbrooke, Que., general contractors for the Registry Office and Municipal Hall now in course of erection, will do all work except heating, plumbing and electrical work.

CONTRACTS AWARDED

Berlin, Ont.
The contract for installation of electric wiring and fixtures at the Post Office has been awarded by the Department of Public Works, Ottawa, to A. Lockhart & Company, Berlin.

Hull, Que.
The general contract for the erection of a church on Chaudiere Street for the Parish of the Holy Redeemer has been let to Noel & Monette, St. Patrick Street, Ottawa. Estimated cost, $150,000.

London, Ont.
The contract for installation of wiring and electric fixtures at the County Buildings has been let to the Benson-Wilcox Electric Company, 264 Dundas Street.

Business Buildings and Indu - trial Plants

Arkona, Ont.
H. Johnson is having plans prepared for barns to cost about $3,000. Work will start in the spring. Frame construction, concrete foundation, shingle roofing.

Barrie, Ont.
The Bell Telephone Company propose to build an office building on Elizabeth Street. Manager, A. G. Price.

Bathurst, N. B.
W. J. Kent & Company, Ltd., intend to rebuild their premises immediately. Brick construction.

Brampton, Ont.
The Omeka Farms have purchased about 300 acres and intend to build a number of cottages, workships, chapel and school. Architect not yet appointed. Superintendent, J. A. Mundell, Box 38, Brampton.

Campbellford, Ont.
The Northumberland Paper & Electric Company are making arrangements for the rebuilding of their plant, and work may start shortly.

Davidson, Sask.
The erection of a garage is contemplated by E. R. Mann & Son, Railway Street.

Chatham Township, Ont.
Gordon Mayville, Chatham Gore, is considering the erection of barns to replace those recently destroyed by fire.

Dungannon, Ont.
The erection of a store and residence is contemplated by Allen & McFarlane, R. R. No. 1 Dungannon. Estimated cost, $4,000.

East Branch, Ont.
W. McKarl, Wallaceburg, Ont., is preparing plans for barns to be erected in the spring. Estimated cost, $3,000.

Fort William, Ont.
Plans are being prepared for a feed mill to be built on River Front for the Ogilvie Flour Mills Company, Ltd. Architects, Barnett & McQueen, Christina Street. Reinforced concrete construction, pile and concrete foundation. Estimated cost, $150,000.

D. A. Gordon, Luci Court, is preparing plans for an elevator to be built for Guy & Company, 406 Grain Exchange Building. Crib construction, pile and concrete foundation. Estimated cost, $20,000.

Kedgwick, N. B.
Work will start shortly on the erection of a lumber mill for the Richards Manufacturing Company. Plans have been prepared by R. McLean, builder. Frame construction, fireproof roofing. Estimated cost, $4,000.

Lindsay, Ont.
Horne Bros., William Street, are having plans prepared for woollen mills Manager, Alexander Horne.

Loretteville, Que.
Work is about to start on the erection of a sawmill for J. Boule. Wood, cement and metal construction. Estimated cost, 10,000.

Mimico, Ont.
The Grand Trunk Railway Company propose to build a station and a conference will be held to decide upon site and other details. Clerk to the Village Council, A. J. Telfer.

Moncton, N. B.
Albert Sincennes, 642 Main Street, is preparing plans for a store building to be erected for W. S. Smith, Main Street. Tenders will be called early in March. Approximate cost, $8,000.

Ottawa, Ont.
Horwood, Taylor & Horwood, 130 Sparks Street, are preparing plans for a rink to be erected on Argyle Street. Work may proceed in the near future. Owner's name withheld.

Pelee Island, Ont.
Sketch plans of a store and warehouse are being prepared for Norman MacCormick by J. C. Pennington, La Belle Building, Windsor. Concrete and brick construction.

Peterboro, Ont.
Plans are in course of preparation for a store house and elevator to be erected on George Street for the Campbell Flour Mills, Company, Ltd., George Street. Concrete foundation, galvanized corrugated iron construction. Head office of Company, Cawthra Avenue, Toronto.

Quebec, Que.
The Quebec Central Railway, Sherbrooke, Que., are building an office and freight shed by day labor under the supervision of J. A. Shield, 34 Dalhousie Street. Frame construction, metal and asbestos roofing. Approximate cost $8,000.

Saskatchewan Province.
Tenders on the erection of stations at Admiral, Scotsguard and Meyronne for the Canadian Pacific Railway will be received until noon, April 1st, by the Division Engineer, T. C. McNabb, Moose Jaw. Plans, etc., with the Division Engineer and with the following Resident Engineers:—J. G. Sullivan, Winnipeg, M McKenzie, Regina, C. S. Moss, Moose Jaw and E. A. Kelly, Saskatoon.

Selkirk, Ont.
J. W. Holmes contemplates the erection of a store at an approximate cost of $5,000.

Smooth Rock Falls, Ont.
The Mattagami Pulp & Paper Company, Ltd., are about to start work on the construction of a sulphite mill. The company also propose to build a sawmill and a model town for their employees. General Manager, A. G. McIntyre, 706 Traders Bank Building, Toronto.

Sorel, Que.
The City Council are considering the erection of a Fire Hall. Particulars from Clerk.

Stratford, Ont.
T. G. Hepburn, 29 Downie Street, is preparing plans for an addition to the premises of the Williams Trow Knitting Company, St. Patrick and Erie Streets. Work includes the installation of a freight elevator.

St. Jerome, Que.
The St. Jerome Manufacturing Company, Ltd., will call for tenders in the early spring for the erection of an addition to their factory. Stone, brick or cement block construction.

St. John, N. B.
F. Neil Brodie, 42 Princess Street, is preparing plans for alterations to the premises of J. M. Roche, King Street.

Three Rivers, Que.
The Canada Iron Corporation propose to make an addition to their plant.

Toronto, Ont.
Work is about to start on alterations to the theatre owned by John Wollson, 1184 Queen Street W. Seating capacity is to be more than doubled.

Vancouver, B. C.
The Department of Public Works, Ottawa, will receive tenders until 4 p. m., March 23rd, for the erection of a freight shed on the Government Wharf. Plans and specifications at office of the District Engineer, Victoria, with the Postmaster, Vancouver, and at the Department. Specifications only at office of MacLean Daily Reports, Ltd., 25 Charlotte Street, Toronto.

Wainwright, Alta.
Tenders on the erection of a flour mill for the Wainwright Milling Company will be called early in April. Architects, C. E. Bird & Company, 616 Corn Exchange, Minneapolis. Approximate cost, $35,000.

Walkerton, Ont.
Frank Antona is considering the erection of a brick warehouse and store.

Walsingham, Ont.
D. A. Langfield is having plans prepared for a barn, estimated to cost $3,000. Timber construction, stone and concrete foundation.

Weston, Ont.
The recently incorporated Weston Golf Club, Ltd., will build a club house in the spring and make alterations to existing buildings. H. J. Church, Main Street, is an interested party.

Windsor, Ont.
Walker & McPhail, Tuson Building, are preparing plans for alterations to a store on Ouellette Avenue for the Heintzman Piano Company. Estimated cost, $3,000.

J. C. Pennington, La Belle Building, is preparing plans for a warehouse to be built on Glengarry Street for Salzenstein Bros., Erie Apartments, Erie Street. Concrete block construction, concrete foundation, composition paper roofing. Estimated cost, $3,000.

Wingham, Ont.
W. Leppard is considering remodelling his hotel and the erection of new stables, at an approximate cost of $4,000.

CONTRACTS AWARDED

Belleville, Ont.
The Department of Public Works, Ottawa, have let the general contract for the erection of a freight shed, etc., to E. Conroy and H. Hickey, 417 Stewart Street, Peterboro.

Dundas, Ont.
The Public Utilities Commission have let the general contract for the erection of an office and store to the Dickson Building Company, Ltd., King Street.

London, Ont.
The contract for plumbing required in connection with the car barns which have been built for the London, Port Stanley Railway Board has been let to Noble & Rich, 237 Queen's Avenue, at $4,195.

Montreal, Que.
The sub-contract for reinforcing steel required in connection with the erection of a grand stand at the Blue Bonnets Race Track has been awarded to W. H. Wardwell, 413 New Birks Building.

The general contract for repairs to the Hotel Prince for J. Pullam, 858 Tupper Street, has been let to M. B. Shaw, 151 Metcalfe Street.

In connection with the store and residences which have been erected for E. Gagnon, 525 Dandurand Street, the brick work contractor is J. Perron, 393 First Avenue, Rosemount, and the electrical work has been let to Lafreniere & Bissonnett, 377 Fifth Avenue, Rosemount.

Work has been started on the erection of five stores and residences on Mount Royal Avenue. The general and masonry contracts have been let to William Boivin, 317 Fourth Avenue, Rosemount, and the brick work to Primiano Lopa, c|o the general contractor. Tenders on smaller trades are now being received by the general contractor. Owner's name withheld.

Rock Island, Que.
The general contract for the erection of a factory and store for G. &. G. Ltd., Stanstead, has been let to Loomis, Dakin Ltd., St. Gabriel Street, Sherbrooke, and work has been started. Estimated cost, $15,000. This work has been previously reported as being at Stanstead.

Stratford, Ont.
The general contract for the erection of an addition to the factory of the Avon Hosiery Company, Erie Street, has been let to Kalbfleisch Planing Mill Company, 106 Milton Street, the brick work to F. Marson, c|o the general contractors, and the plastering to W. Soeder, 210 Huron Street. Estimated cost, $12,000.

The general contract for alterations and additions to the Sunday School of St. Andrew's Church has been let to R. L. Oman, 24 Earl Street. Work includes the erection of a gallery.

Toronto, Ont.
Work has been started on the erection of an addition to the engine room of the Harris Abattoir Company, Ltd., Union Stock Yards. The contract has been let to Wells & Gray, Confederation Life Building. Brick construction. Estimated cost, $7,000.

The general contract for alterations and additions to a factory on Strachan Avenue for the W. K. Kellogg Cereal Company, Battle Creek, Mich., has been awarded to J. Rees, 705 Manning Avenue.

Whitebread, Ont.
N. Young and T. Kilbride, Wallaceburg, Ont., have let contracts for steel barns to H. A. MacDonald, Whitebread. Steel frame construction.

Windsor, Ont.
The Windsor & North Essex Agricultural Society have let the following contracts for the erection of an addition to the agricultural building at the Race Track:—masonry, R. Wescott, 55 Oak Street; carpentry, W. Dupuis, 147 Dougal Street; roofing and plumbing, Pennington & Brian, Sandwich Street E.; painting, Lossing & Harris, 109 Church Street.

Residences

Aldershot, Ont.
Tenders will be called shortly for the erection of a residence for F. W. Easterbrook. Architect, J. A. Armes, 68 Federal Life Building, Hamilton. Pressed brick construction, tile foundation, shingle roofing. Estimated cost, $5,000.

Ameliasburg Township, Ont.
W. W. Anderson, Rossmore, Ont., proposes to rebuild his residence this season. Estimated cost, $4,000.

Atwood, Ont.
George Gordon, Main Street, is having plans prepared for improvements to ris residence. Work will include veneering with white brick.

Exeter, Ont.
Mrs. T. Brock is considering the erection of a residence, estimated to cost $3,000. White brick construction.

The erection of a residence is contemplated by H. Jones & Son. Brick construction. Estimated cost, $3,000.

Fred Brock is considering the erection of a residence. Brick construction. Estimated cost, $3,000.

Charles B. Snell contemplates the erection of a residence at an approximate cost of $3,000. Brick and concrete construction.

London, Ont.
George Mills, 527 Dundas Ctreet, proposes to build a residence in the spring. Estimated cost, $3,000.

Albert Vincent, c|o R. C. Struthers & Company, is considering the erection of one or two residences in the spring, and will prepare plans. Estimated cost, $3,000 each.

Frank Moore, 25 Kensington Street, contemplates the erection of two residences, estimated to cost $5,000. Plans will be prepared.

Meaford, Ont.
The erection of a residence is contemplated by William McCutcheon, Garryowen, Meaford. Owner will prepare plans.

Montreal, Que.
Henri Demers, 1379 De La Roche Street, has commenced the erection of four flats, estimated to cost $5,000, and is receiving tenders on roofing, heating, plumbing and electrical work. Brick construction, stone foundation, felt and gravel roofing.

E. Pepin, 129 Marlowe Street, is receiving tenders on roofing, heating, plumbing and electrical work required in connection with the flats which he is building. Brick construction, concrete foundation, felt and gravel roofing. Approximate cost, $4,000.

Orford Plains, Ont.
John B. McDonald, Orford Plains, Rodney, Ont., proposes to remodel his residence. Work will include veneering.

Ottawa, Ont.
Work is about to start on alterations to apartments on Laurier Avenue W. for Donald Fraser, 82 O'Conner Street. Most of work will be done by owner. Estimated cost, $3,000.

The Oakland Land Company, 1111 Bank Street, are considering the erection of a number of residences at an average cost of $4,500. Brick veneer construction, stone foundation, shingle roofing. Plans will be prepared.

Outlook, Sask.
J. A. Fraser intends to build a residence this summer. Estimated cost, $5,000.

Quebec, Que.
A. Z. Lefebvre, 109 Marie Louise Street, has commenced the erection of a residence, estimated to cost $5,000. Brick and frame construction, stone foundation, metal and asbestos roofing.

St. Jerome, Que.
A. Vaillancourt, Labelle Street, will call for tenders early in the spring for the erection of a residence. Brick and frame construction.

St. John, N. B.
A bill will be presented at the next sitting of the Provincial Legislature to authorize the City to build homes for working men. Clerk, H. E. Wardroper.

Sutherland, Sask.
Tenders will be received until 4 p. m., March 23rd, by R. C. Desrochers, Department of Public Works, Ottawa, for the erection of a boarding house at the Forest Nursery Station. Plans and specifications at offices of W. T. Mollard, Clerk of Works, Regina, the Superintendent, Forest Nursery Station, Sutherland, with the Postmaster, Brandon, and at the Department. Specifications only at office of MacLean Daily Reports, Ltd., 25 Charlotte Street, Toronto.

Toronto, Ont.
Tenders on wiring and lathing required in connection with the residence which has been erected at 1238 Kingswood Road are being received by G. H. Wallace, 236 Kingswood Road.

Tenders are being received by W. B. Galbraith, 22 St. Leonards Avenue, for the erection of a residence at Lawrence Park. Hollow tile and brick construction. Estimated cost, $7,500.

Warwick Township, Ont.
Malcolm Perry, R. R. No. 2, Watford, Ont., contemplates the erection of a residence.

Wesley McKay, R. R. No. 2, Watford, Ont., is considering the erection of a residence.

Windsor, Ont.
Peter Octerhout, 23 Pitt Street E., is preparing plans for a number of bungalows to be built on Pierre and Lincoln Streets. Frame construction, concrete foundation, shingle roofing. Estimated cost, $3,000.

CONTRACTS AWARDED

Montreal, Que.
W. L. Ployart, 181 Harvard Avenue, has let the general contract for the erection of a residence on Grosvenor Avenue to Anglin's Ltd., 65 Victoria Street. Work will start in the spring. Brick construction, concrete foundation, felt and gravel roofing.

Ottawa, Ont.
In connection with the residence in course of erection for William Eastman, 24 Ossington Avenue, the contract for plumbing has been let to Gervin & Lillico, 1095 Bank Street, and the electrical work to the Dominion Electric Company, 477 Sparks Street.

The general contract for the erection of a cottage on Williard Street for McLeod McAllister, 22 Glen Avenue, has been awarded to J. E. Cooper, 514 McLeod Street. Brick veneer construction, concrete foundation, shingle roofing. Estimated cost, $3,000.

Walkerville, Ont.
In connection with the bungalow to be built on Lincoln Road by the Burns & Walker Construction Company, Tuson Building, Windsor, the plumbing has been awarded to Roy Hicks, 159 Wyandotte Street E., Windsor.

Power Plants, Electricity and Telephones

Chesley, Ont.
Krug Bros. Company, Ltd., are in the market for electric motors, 500 volt, d. c., 5 to 10 h. p.

Dungannon, Ont.
The Goderich Rural Telephone Company, Ltd., propose to make extensions to their system this year.

Emerson, Man.
The Town Council are considering the installation of an electric lighting plant. Clerk, W. W. Unsworth.

Marieville, Que.
The Town Council are considering the installation of an alarm system at an approximate cost of $2,000. Clerk, J. E. Ostiguy.

Pelee Island, Ont.
Albert Muir, c/o Pelee Island Telephone Company, has been appointed to look after extensions and other improvements to the Company's system.

Saskatchewan Province.
The Beadle Rural Telephone Company have been empowered to borrow $4,300 for the construction of their system. Chairman of the Local Government Board, A. J. McPherson.

Whitby, Ont.
The Town Council have instructed the Property Committee to report on the installation of a new fire alarm system. Clerk, Joseph White.

Fires

Beauport, Que.
The Parish Church has been destroyed by fire. Loss, $3,000, partially covered by insurance. Curate, L. A. Deziel.

Bowden, Alta.
The business block owned by C. A. Johnston has been destroyed by fire. Loss, $30,000, partially covered by insurance.

Fort William, Ont.
St. Luke's Presbyterian Church has been damaged by fire and the organ entirely destroyed. Total loss, $5,000.

Moncton, N. B.
The plant of the Record Foundry & Machine Company has been damaged by fire to the extent of about $100,000. Loss is covered by insurance.

Sherbrooke, Que.
Fire has damaged the interior of the Queen's Hotel to the extent of about $4,000. Owner, D. McManamy, 6 Gordon Street.

Sydney Mines, N. S.
The residence of John Barrington, Street, has been destroyed by fire.

Toronto, Ont.
Fire has damaged the warehouse of the William Rennie Company, Ltd., 130 Adelaide Street E., to the extent of about $7,000. Loss is fully insured.

The building owned by James Carnell, 1922 Dundas Street, has been damaged by fire. Loss, $2,100.

Miscellaneous

Brantford, Ont.
The Chairman of the Board of Works will receive tenders until noon, March 13th, on the supply of road oil during the year. Estimated quantity, 120,000 gallons. Specifications at office of the Engineer, T. H. Jones.

London, Ont.
The Fire Chief has recommended to the City Council that an auto tractor and combination waggon be purchased, as well as 1,000 feet of 2½ inch fire hose. Clerk, S. Baker.

Merlin, Ont.
The Town Council are considering the purchase of fire fighting equipment. Particulars from Dr. Bell.

Moose Jaw, Sask.
Tenders on the excavation of a reservoir above the dam for the Canadian Pacific Railway Company will be received until noon, April 1st, by the Division Engineer, T. C. MacNabb, Moose Jaw. Plans, etc., with the Division Engineer, with J. G. Sullivan, Chief Engineer, Winnipeg, M. McKenzie, Resident Engineer, Regina, C. S. Moss, Resident Engineer, Moose Jaw, and with E. A. Kelly, Resident Engineer, Saskatoon.

New Glasgow, N. S.
The Department of Public Works, Ottawa, have extended the time for receiving tenders on the construction of lock gates for the East River Lock until March 13th.

Peace River, Alta.
The Town Council have secured a loan for the purchase of fire fighting equipment. Secretary, A. E. Carlisle.

Saanich, B. C.
Fire Chief Davis will recommend the establishment of three or four fire stations equipped with reels, short ladders and hose. Municipal Clerk, Hector S. Cooper, Municipal Hall.

Walkerville, Ont.
The Canadian Hoskins Ltd., Sandwich Street, are considering the purchase of machinery for the manufacture of wire

goods. Estimated expenditure, $10,000. Manager, R. H. Cunningham.

CONTRACTS AWARDED

Cornwall, Ont.
The Town Council have let a contract for the supply of a boiler and pump to John Inglis Company, Ltd., 14 Strachan Avenue, Toronto, at $2,800.

Montreal, Que.
The Harbor Commissioners, Common Street, have awarded the contract for the supply of Douglas Fir to Mason, Gordon & Company, 80 St. Francois Xavier Street.

The Harbor Commissioners have let the contract for the supply of elm and maple timber and hemlock railway ties to W. H. Kelly, Buckingham.

The City Council have let the contract for the supply of 15,000 tons of sand to J. Aybram, Ste. Emelie de Joliette, Que., and for 200 tons to the Touzin Sand Company, Ltd., 76 Common Street, Montreal.

Tilbury, Ont.
The Union Natural Gas Company, Sarnia, Ont., have let the contract for supply of gas pipe to the National Supply Company, Queen Street E., Tilbury. Approximate cost, $300,000.

Quebec, Que.
La Banque Nationale, 75 St. Peter Street, have let the contract for the erection on St. Foye Road to C. E. Morissette Ltd., 208 Latourelle Street. Estimated cost, $6,000. Brick construction.

West Wawanosh Township, Ont.
The general contract for the erection of a school for the Trustees of School Section No. 4 has been awarded to J. W. Henderson, Lucknow, Ont. Seating, slate blackboards, hot air heating system and other equipment will be purchased by the Secretary, William McQuillan, R. R. No. 4, St. Helens P. O.

Weston, Ont.
A. J. Barker will shortly start work on the erection of a garage on Main Street. Estimated cost, $10,000.

Winnipeg, Man.
Work is expected to start immediately on the erection of the first unit of the proposed store for the T. Eaton Company, head office, Yonge Street, Toronto. The structure will be erected in four units, the last of which will be a new building on the site of the present store. Approximate cost of first unit, $300,000. Fireproof construction, stone facings. Chief Engineer, George W. Thomson, c/o the Company.

Late News Items

Campbellton, N. B.
The Town Council are considering the expenditure of $25,000 on the erection of a Town Hall, and of $5,000 on a street lighting system. Clerk, J. T. Reid.

Dundee Township, Que.
Tenders on the construction of six small concrete bridges will be received until 10 a. m., March 6th, by the Secretary to the Township Council, T. W. Fraser, Dundee. Plans and specifications with the Secretary.

Flos Township, Ont.
Tenders on the erection of a school for the Trustees of School Section No. 5, Flos Township, will be called very shortly. Architect, J. Wilson, Collingwood, Ont. Brick construction, asbestos roofing. Estimated cost, $21,000.

Fort William, Ont.
Fire has destroyed the store and other premises owned by J. Weisner, 132 Ogden Street. Loss, about $8,000. Owner will probably rebuild.

Halifax, N. S.
The School Board, Sackville Street, will probably call for tenders shortly on the erection of a school. Architect, H. E. Gates, Queen Building.

The City Council have let the following contracts for the erection of a residence on Grafton Street:—general contract, Falconer & MacDonald, St. Paul Building; painting, David Roche, 35 Blowers Street; heating, Longard Bros., 213 Hollis Street; plumbing, M. Day, 73 Cornwallis Street; electrical work, J. Starr, Son & Company, Granville Street. Approximate cost, $4,500.

Lachute, Que.
The Town Council have awarded the contract for the construction of a bridge over the North River to Lafleur & Berniquer. Steel construction. Estimated cost, $10,750.

Wood-Block Flooring Said to Have Proved Its Worth

It is only a few years that creosoted wood blocks have been used for the flooring of factories, warehouses and other buildings. Yet they have already proved their worth, judging from information presented at the wood preservers' convention in Chicago by C. H. Teesdale of the U. S. Forest Products Laboratory. Mr. Teesdale has summed up and tabulated the answers to questions submitted to a large number of users of wood-block flooring, as well as the manufacturers of the creosoted blocks. His summarizing of the data received is as follows:

The results of this investigation indicate that treated wood block makes a desirable type of flooring for many purposes, and it is likely that its use for interior work will increase. Since its large use for these purposes is just beginning, one might expect that unforseen trouble would develop. The records of 160 floors indicate, however, that serious trouble has developed in a very low percentage of cases.

Most of the trouble has come from shrinkage or expansion of the blocks. To prevent these troubles it is necessary to study each case where blocks are to be laid, and to treat the blocks accordingly. For dry situations the blocks should be well seasoned before treatment and laid in the floor while thoroughly dry. In wet or alternately wet and dry situations dry blocks would give expansion trouble, hence the timber should be green or only semi-air-dry when laid. Even dry interiors are liable to be accidentally subjected to water, however; hence it would seem desirable as a rule to use bituminous fillers instead of sand filler.

Sand cushions were probably a source of trouble in several cases. If there is any vibration, or if the sand is at all liable to shift, a bituminous or cement grout cushion is to be preferred. Sand cushions are also liable to cause uneven floors if the blocks shrink, and it seems likely that many cases of shrinking would not give serious trouble where bituminous filler and bituminous or cement grout cushions are used.

Bleeding caused very little trouble. In dry and very warm situations, where it is most likely to occur, it would be desirable to consider carefully the method of treating and handling the blocks in order to avoid objectionable bleeding.

In a few cases it seems likely that good block should not be used. For example, it should not be used where butter or tobacco products are stored. In some foundries, where hot castings are thrown upon the floor, the blocks have burned through to the foundation. Wood blocks may be objectionable where the soiling or staining of certain classes of merchandise would lower the value, and in one case where used in a tennis court wood blocks were a failure and had to be removed.

Wood block has been found to be very satisfactory in many cases where heavy castings are thrown about or where heavy trucks are moved, and it is liked by workmen because it is warm and easy on their feet.

The replies from the users of wood-block flooring indicate quite strongly that when new wood-block floors are to be laid a careful investigation of all the conditions existing or likely to develop should be made by the manufacturer. The method of treatment and construction of the floor should then be adapted to the special conditions found. If this is not done many cases of dissatisfaction are very liable to develop.

Deflector Gives Direct-Reading of Building Settlements

A direct reading deflectometer was used in determining the cause of the usual initial settlement in buildings being underpinned along the New York subways. This deflectometer was never used in this country before according to Maurice Deutsch, consulting engineer, New York City, who used it to make some original tests of piles on this work in September last year. In consists of a steel tape about ½ in. wide attached to the pile being tested and run vertically up and along a small wheel at the end of a horizontal shaft. At the other end of this shaft an index needle is set and revolves around a calibrated dial marked in millimeters, thus giving very exact indications of pile movement.

Light-Soil Roads Not Suitable for Traffic Unless Surfaced

When highway traffic exceeds 2,000 tons per year on roads constructed of light soil it is time to adopt some form of hard surfacing, according to a statement by A. P. Anderson, highway engineer, in the Reclamation Record. Dragging many of these roads has not the cumulative effects, such as obtain on clay roads, as the only binding power is the capillary moisture lost when the road gets dry. The maintenance must be directed toward retaining the moisture by incorporating with the surface soil some natural binder, such as clay or adobe, or adding some temporary fibrous binder, such as straw or sage brush. In irrigated districts flooding is worth considering, one side at a time, or, where the rate of lateral percolation is rapid, flooding the side ditches.

Proper Consistency of Concrete

UNSATISFACTORY concrete will result from the very best of aggregates if they are not properly proportioned. The too prevalent unscientific method of arbitrary selection, at present in general use, would scarcely seem to have been justified even by the added facility with which the work can be constructed.

W. S. Gearhart, Chairman of the Committee on Proportions of Materials and Consistency of Concrete, recently pointed out to the Conference on Road Building held in Chicago that if concrete were specified to withstand certain tension, compression, abrasion and absorption tests, and to be subjected to expert inspection, most of the difficulties and failures from faulty proportioning of aggregates could be removed. The requirements for consistency should be more definitely specified. The present terms used in defining consistency are altogether too indefinite to the ordinary contractor. Consistency could probably best be defined by describing how the concrete should act and the form it should take when deposited.

Until some form of apparatus is devised and a systematic method of inspection established little can be done to overcome the present unsatisfactory consistency specifications. Having concrete too wet should be especially guarded against, since wet concrete gives a material inferior in quality and strength to concrete of a medium or quaking consistency. Experiments with hydrated lime in concrete seem to indicate that it decreases the percentage of voids, produces a more impervious concrete, reduces expansion and contraction under moisture changes, and prevents segregation. In spite of the wonderful progress that has been made in concrete work we are evidently still very considerably in the dark as to its scientific preparation. The report of Mr. Gearhart mentioned above, published elsewhere in this issue gives interesting and valuable information on this important subject.

Advantages of Winter Building

The question of winter building is one that of necessity must be decided by the owner himself, and he is generally not sufficiently informed to take the chance. All kinds of mason work are now carried on successfully at all times during the winter. Buildings of reinforced concrete, depending almost entirely upon concrete for support, are erected in the dead of winter. Mortar will not set as rapidly in winter as in summer, but mortar used in winter will become more durable than mortar used in summer. One reason for this may be that brickwork laid in summer absorbs the moisture from the mortar before it has had time to set.

It is an accepted opinion of the public that contracts for winter work can be let at a lower price than at any other time of the year, all things being normal. It is probable that about 10 per cent. of the cost of the building can be saved if contracts are let during the winter.

The man who erects his building in the winter has the advantage of securing the higher class of workmanship represented by the more competent mechanics who are kept on the pay-roll during that period. Furthermore, as the contractor and architect are not rushed with the same amount of work as in the summer, each can devote more of his individual time to the construction of the building.

All woodwork which enters into the construction of a building is far superior when installed during cold weather, the atmosphere being much dryer than in summer. Much of the moisture in the form of rain, which is absorbed by the rough woodwork during warm weather, becomes snow in winter and is easily cleaned off before any material damage can be done. The moisture absorbed by the rough woodwork in summer will not dry out until some time after the building is completed and decorated. When this moisture dries out floors and partitions often settle, causing cracks and other defects.

One of the greatest objections to summer building is the absorption of moisture from the air by the interior wood finish. This interior finish is one of the most important features of a building, and greater care and skill must be employed in its installation than with any other part of a building. It is always subject to more close inspection as long as a building stands, and it is important that every precaution should be employed to preserve the highest class of workmanship in the building as a whole. The moisture absorbed by the finish woodwork in summer will dry out later and cause joints to open, doors to shrink, panels to crack, and the work to assume the character of a building that literally has been thrown together.

On the other hand, heat is maintained in the building erected in the winter, and, as a result, moisture is kept out and the finish remains in a first-class condition.—The Plumber.

Unloading Stone Economically

Editor, Contract Record:—

One of the most troublesome and expensive problems that confront the Road Superintendent where stone has to be shipped in by rail, is the unloading.

Few men are willing to go in a car, especially on a warm day and shovel stone, and except men are used to the work, not much progress is made. Many devices have been invented to overcome this difficulty, some have been tried out with more or less success. The Toronto and Hamilton Highway Commission have a steam derrick with a Clam Shell Dipper which is fairly successful, but this device is too expensive and not portable enough for county work.

It has occurred to me that a light derrick worked by a Gasoline engine with a Clam Shell Dipper that could be easily taken down and moved from station to station, would be a great help. This device could be set up some distance from the loaded car to give the boom room to work and the crushed stone discharged into the wagon or a bin from which it could be loaded. It is strange that some enterprising firm has not put something of this description on the market. Derricks of all designs and capacity are manufactured by many firms but none I have examined seem to be what is required for this particular work.

Yours truly,
James M. Sheppard,
Road Superintendent.
Queenston, Welland Co.

Gravity Filter System for Drummondville

Messrs. Ouimet & Lesage, engineers, of Montreal, have designed a pumping station and mechanical gravity filter system for the town of Drummondville, P. Q., to replace the present one which has been found inadequate to meet modern conditions. The plans provide for a plant of 1,500,000 U. S. gallons capacity per twenty-four hours, but it is proposed to now install two of the three units, each with a capacity of 500,000 gallons; the existing reservoir will be utilized. The water will be taken from the St. Francis River, and will be automatically purified by filtration, alum solution, and liquid chlorine. The chlorine is to be fed through a Venturi meter into the filtered water. The sedimentation basin will have a capacity of 140,000 gallons, and the clear water basin one of 80,000 gallons. Each filtering unit will be operated by hydraulic valves, the action being on marble tables in front of each unit. The four pumps—two high lift and two low lift—will be driven by electric and gasoline motors, the latter to be used as auxiliary forces. The electric current will be supplied by the Southern Canada Power Company. The pumping station and filtration plant will be of concrete and pressed brick, the buildings being made fireproof as far as possible. The former structure will be heated by a hot water system.

Moldless Concrete Construction

A new phase in Portland cement concrete construction which should prove of practical value to contractors and builders has recently been developed, and many ingenious details of construction have been worked out to take care of practical problems which the contractor encounters on the job. This new plan is the erection of reinforced concrete without the use of forms or molds of any kind; the only special equipment necessary being a few inexpensive gauge strips and tamps. The walls in this construction are made up of concrete panels, molded flat on the ground and confined within light steel channels (known as metal lumber). The channels are held apart by steel rods which also serve to reinforce the concrete. When the panels are assembled, the channels come together back to back, and are easily locked in place. The method of concrete building construction is claimed to be revolutionary in its simplicity, low-cost, and adaptability.

"Ladies Night" in Calgary

The Calgary Branch of the Canadian Society of Civil Engineers held its third dinner of the season at the Palliser Hotel, Thursday evening, February 24th. An innovation was tried at this meeting. It was designated as "ladies night" and all present agreed that it was a success.

After the dinner Dr. J. G. Rutherford, Superintendent of Agriculture and Animal Industry, C. P. R., Department of Natural Resources, addressed the Branch on the subject "Some Thoughts on the Present World Situation."

In his remarks the speaker referred to the remarkable development in the world during the past hundred years, which might justify one in saying that the world as we know it is not more than a hundred years old.

Within that time there had been the wonderful spread of transportation facilities, the development of the lighting system and the spread of education, for about one hundred years ago the number of people who could read and write was about equal to those who could not do so now. Dr. Rutherford first saw the electric light in 1880 and the telephone, which is now in such general use, he first utilized in 1878.

While this development was going on there had been an era of wastefulness which he said would compare to a financial drunken spree. The resources of the country had been wasted and now the penalty must be paid. Had we husbanded our wealth instead of wasting it Canada would have been better prepared for the present struggle.

In the absence of William Pearce, Chairman, A. S. Dawson, Chief Engineer, Department of Natural Resources, C. P. R., occupied the chair.

Toronto Section C. S. C. E.

The regularly monthly meeting of the Toronto branch of the Canadian Society of Civil Engineers will be held in the Society's rooms at the Engineer's Club, 90 King Street West, on Thursday, March 9, at 8 p. m. The work of the Committee appointed in 1915 to suggest desirable changes in, or additions to, the present by-laws will be discussed.

The Clays of Southern Saskatchewan

Canada Well Supplied With an Abundance of High Grade Clays—Suitable for Manufacture of Refractories, Stoneware, White Earthenware, Structural Products

By N. B. Davis*

IN the southern part of the province of Saskatchewan there is located one of the most valuable and extensive clay fields of the Dominion of Canada. From the vicinity of Estevan, westward along the international boundary some two hundred and fifty miles, and north to make a triangular area with the apex west of Moose Jaw, the country is underlain by a series of clays, silts, sands and lignites, comprising what is known to geologists as the Fort Union formation. West of this again, smaller detached areas of this same formation outcrop in those elevated areas known as Boundary Plateau, White Mud River Plateau, and the Cypress Hills.

Although the Fort Union formation is known to generally underlie these areas, the valuable clays are not available everywhere over them. It is only in the escarpments of the plateaus, and in the large river valleys, with their tributary coulees, that good workable sections of the clays are to be found.

The most important beds of this formation, to the clayworker, are the white and grey refractory clays and clayey sands, constituting what are locally known as the "white muds." The white plastic clays are of stoneware character, fusing around cone 15. The more sandy beds are quite refractory, some of them standing up to cone 30.

These refractory clays are followed in importance by yellow calcareous clays and clay silts, which are suitable for common clay ware, such as brick and drain tile; and for mixing with the stoneware clays to reduce the temperature of vitrification in making sewer pipe and hollow block.

Dark grey, brown, and black, gumbo-like clays occur in the same formation, but their drying defects are so bad that they cannot be used without special preliminary treatment, such as the pre-heating practised at Estevan.

Lignite beds of fair quality are here and there associated with the clays, and their economic aspects are of great importance to the future of the clayworking industry. The accompanying sketch map (Fig. 1) shows the general distribution of the clay-bearing Fort Union formation, the important clay outcrops being suitably indicated.

It will be noticed that the largest area includes the elevations known as Wood Mountain and the Dirt Hills, and in the following notes these localities, along with other prominent topographical features, such as the Frenchman Valley, Souris Valley, and Cypress Hills, will be used as headings.

Cypress Hills

The section of clays found in the Cypress Hills is the most complete one in the province. The hill tops are protected at the highest elevations by quartzite gravel, the pebbles of which should prove of value for grinding purposes. Below the gravel there is a great thickness of fine, plastic, greyish white, to mottled red and green clays. They are best exposed near the western end of the hills. Some of these are slightly calcareous. Their working qualities are excellent.

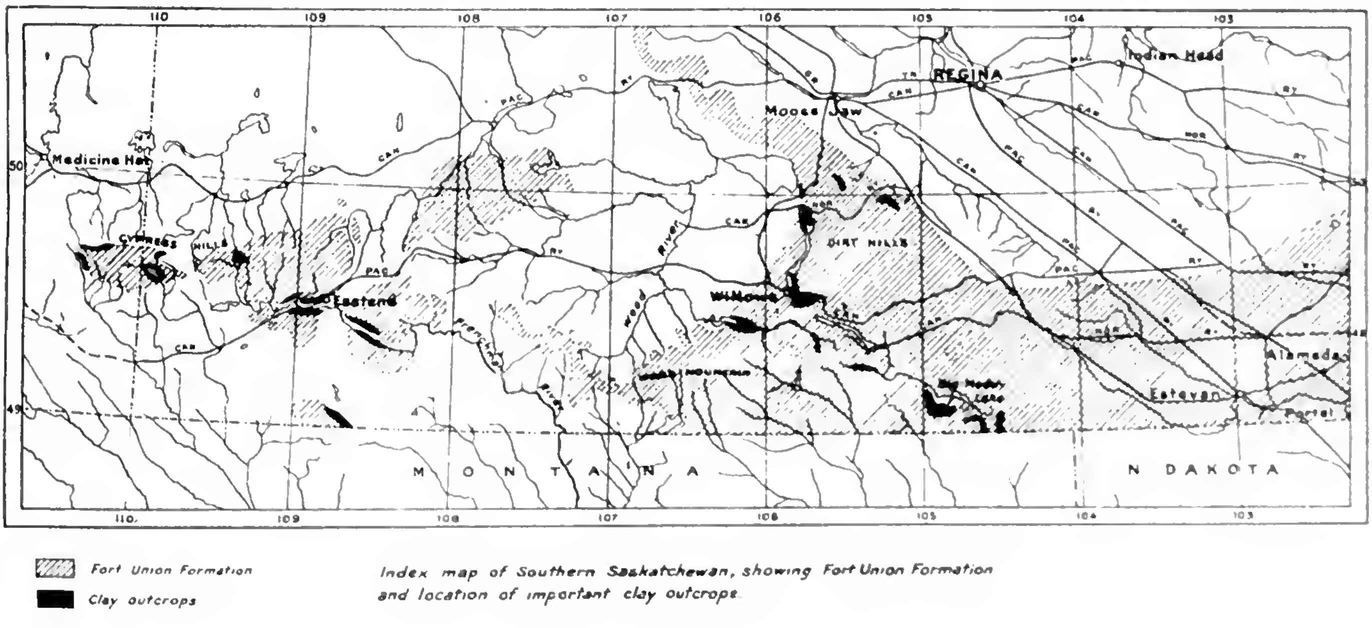
The white refractory clays are not exposed here, but continuing eastward, easily worked outcrops are to be found near old Fort Walsh, on Battle Creek, and in the valley of the White Mud or Frenchman River, the most important locality being the last named.

From Palisade to South Fork the Canadian Pacific Railroad follows the deep valley of the Frenchman River and Swift Current Creek coulee. For most of this distance, some fifteen miles, the white clays can be seen outcropping in the valley sides within a mile or so each side of the railroad.

A typical section measured in the vicinity of Ravenscraig resulted somewhat as shown in Fig. 2.

It will be noted that the white clays are underlain by a considerable thickness of greyish-white quartz

* Mines Branch, Ottawa, before C.N.C.P.A., Toronto.



Index map of Southern Saskatchewan, showing Fort Union Formation and location of important clay outcrops sands, which may prove of value for moulding or glass making.

The yellowish calcareous clays, silts and sands overlying the white clays are quite thick, but erosion has here and there made the white clays available without underground mining operations being necessary.

The beds are all more or less lenticular, all through the Fort Union formation; they thicken and thin from place to place. Along the Frenchman River the good clays appear to increase in thickness eastward, while to the west the beds are more sandy.

In the vicinity of the town of Eastend, where the railroad leaves the valley of the Frenchman River, the best workable outcrops are to be found. To the north and south of the town, erosion has bared considerable quantities of the valuable white clays: in one outcrop the following section was measured: (1) glacial drift, 1 to 10 ft.; (2) brown clay, 8 ft.; (3) fine yellow sand, 2 ft.; (4) plastic white clay, 5 ft.; (5) purplish grey clay, 2 ft.; (6) white plastic clay, 6 ft.

The clays below the glacial drift at this point have good working qualities, with shrinkages within practical limits. They burn to dense, greyish bodies at cone 5, and do not soften until the deformation of cone 15. The Albany slip, Bristol, and salt glazes have been applied, with success, to these bodies.

The glacial clay silt of the valley bottom near Eastend burns to a fine deep red color at cone 010. A small quantity of sand would have to be added to the clay,

Fig. 2—Section of Fort Union Beds near Ravenscraig, Sask.

however, to dry it without cracking. It could then be used for the manufacture of hollow building block and common brick.

Wood Mountain

Between Eastend vicinity and the northwest slope of Wood Mountain the country is heavily covered by glacial deposits, and the Fort Union clays are hidden.

In the coulees tributary to the Wood River and around Twelve Mile Lake the white clays again appear. A sample of a sandy, white clay, collected on the north shore of Twelve Mile Lake, stood up to cone 28.

Further northeast, in the Lake-of-the-Rivers valley, near Willows Station, on the Canadian Pacific Railway, the Alberta Clay Products Company is working a fine section of the refractory clays, and shipping the run-of-bank some 450 miles, via Weyburn and

Fig. 3—Alberta Clay Products Co.'s pit near Willows, Sask.

Moose Jaw, to Medicine Hat. At this place it is worked into sewer pipe, flue-lining, wall coping, etc. Fig. 3 shows the pit being worked during the summer of 1915.

The run-of-bank burns to a dense, vitrified body at cone 9. A sample of a fifteen-foot bed in this section reflects the properties of a ball clay.

Dirt Hills

The white clays appear further north again in the Lake-of-the-Rivers valley, near Mitchellton, on the Canadian Northern Railway, and, again along the north-facing escarpment of the Dirt Hills. It is here at a place called Claybank that the Saskatchewan Clay Products Company is operating the only plant in Saskatchewan, using the refractory white clays.

The plant consists of the usual pit equipment of cars hauled by cable, a large storage shed, one dry pan, one dry press machine, and eight round down-draft kilns. Power is supplied by a 150 h.p. Diesel oil engine. The white, greyish-white and sandy clays are blended to make dry press face brick of plain buff and flashed colors.

Mr. George Shoemaker is manager of the plant, and at present is carrying on experimental work with the intention of placing fire brick on the market, tests on some of the clays having shown them to stand up to cone 30.

Big Muddy Valley

In the Big Muddy Valley, from Willowbunch Lake, southeast to the international boundary, the white clays outcrop here and there all down the valley. The best exposures are located near the boundary line in the vicinity of Big Muddy post office. Tests on a number of samples from this locality show the clays to be in all respects similar to those found in the other areas described.

Souris Valley

East of the Big Muddy Valley, the white clays are not known to outcrop. The whole thickness of the

Fort Union beds consists of dark grey, broken and yellow clays and numerous lignite seams. The best outcrops occur in the Souris Valley, and more particularly in the vicinity of Estevan, where numerous plants are working the red and buff burning clays for making common and face brick, and hollow block. The red burning clay has to be pre-heated to overcome checking, and is then made into dry press bricks.

The industry is fairly well established in the Estevan field, there being some five plants equipped for operation at the present time.

Railroads and Fuel Supply

Until but recently rail transportation has been lacking to the most valuable clay areas. The Portal-Moose Jaw branch of the Canadian Pacific Railway has served the Estevan field for a number of years, but the important refractory clays do not occur there.

Just two years ago the Canadian Northern Railway completed its Avonlea-Gravelbourg branch as far as Claybank in the Dirt Hills, and made the high-grade clays of this locality available. However, the market for high-class face brick broke about the time the railroad arrived, and the plant at Claybank suffered accordingly. During the past year the same Canadian Northern Railroad branch has been constructed west, and made available the clays of the north end of Lake-of-the-Rivers, near Mitchellton.

Three years ago the Canadian Pacific Railway started its Weyburn-Lethbridge line, and since then has tapped the clays of the south end of Lake-of-the-Rivers, and of the White Mud River Valley. The line is now completed as far west as the Alberta boundary, and it is hoped that the time will not be far distant when connection will be made with the construction east from Lethbridge.

South of the Canadian Pacific Railway the Canadian Northern Railway has a branch line extending westward to near the southeast end of Willowbunch Lake. If this line is completed along the proposed route it will open up the clay and lignite areas immediately to the north of Wood Mountain.

At present most of the fuel used is brought in by rail over the Canadian Pacific Railway from Alberta. It is mostly a semi-bituminous coal, and, because of the long haul, the price is high. In the Estevan field a certain amount of the local lignite is utilized, but its full efficiency it not realized.

Extensive tests, carried on at the fuel-testing plant of the Department of Mines, in Ottawa, have shown the lignites to be ideal for making producer gas for power generation in a gas engine. No steaming tests have been made, but the analyses point to its successful application in this way under suitable mechanical conditions.

The gas producer has come to the clay working industry to stay, and the clayworker of Saskatchewan, and the West generally, should not be slow to adopt it as an economical means of converting a poor fuel to a high-grade one.

Natural gas has not been struck, as yet, in commercial quantities anywhere in the southern part of the province. Preparations are being made to sink a well at Eastend in the hope of getting a cheap fuel to aid in the local development of the clays.

The Future of the Clay Industry

The importance of the clays of southern Saskatchewan to the whole Canadian West cannot be overestimated. There is an abundance of high-grade clays suitable for the manufacture of refractories, of stoneware, Rockingham ware, and white earthenware, as well as for all varieties of burned clay products for structural purposes.

Before the outbreak of the war in Europe, the immediate future of the clay industry in Saskatchewan promised well. The railroads were spreading lines of transportation over the country, crops were fair, and the Western farmer was beginning to appreciate something better than a sod shack to live in. Lumber had to be hauled great distances, and the price was, accordingly, high. Prairie fires were teaching the builders with wood the value of more fireproof construction. Altogether, the country was ripe for a better supply of burned clay products.

With the war on, needs have not materially changed. Business is simply marking time for a better monetary condition. The country is essentially a farming one, and with wild-boom days over, and the war at an end, normal conditions should soon return.

Proportioning and Mixing Concrete

Better Proportioning of Aggregates and More Efficient Inspection Necessary to Procure Best Results from Concrete—Effect of the Addition of Hydrated Lime

By W. S. Gearhart*

It is the common practice at the present time to proportion materials for concrete roads and streets by the method of "arbitrary selection"; that is, by specifying the number of parts of different ingredients. Although this is one of the most unscientific methods of proportioning materials, its general use has seemed to be justified by the facility with which the work can be handled under existing conditions. But unless the character of the aggregates to be used and the quality of concrete made with the specified proportions of ingredients are carefully determined, this method should not be used, for a 1:2:3 mixture in one case may be identical in quality with a 1:2:4 mixture, or even a 1:2½:5 mixture of another, on account of the variation in size of aggregates.

Proper Mixing

Unsatisfactory concrete will result from the best aggregates if they are not properly proportioned. Therefore a careful investigation of aggregates may mean the difference between the success or failure of the road. The general adoption of a more scientific method of proportioning the materials is very much to be desired.

By specifying that the concrete be of a standard quality which would withstand certain tension, compression, abrasion, and absorption tests, probably similar to paving brick specifications, and then by requir

* Chairman of Committee, before National Conference on Concrete Road Building.

ing high-class expert inspection to eliminate the personal equation as much as possible, and so that frequent field tests could be made, most of the principal objections to the scientific methods of proportioning materials for concrete could probably be eliminated.

Recommendations

The recommendations for the proportions of the several classes of concrete for roads and streets represent the best practice at the present time. However, they should not be used without a thorough appreciation of the defects in the method of arbitrary selection. These recommendations are therefore made with the understanding that the Portland cement used complies with the Standard Specifications of the American Society for Testing Materials; that the fine and coarse aggregates will meet the standard specifications for concrete roads and pavements of the American Concrete Institute for 1914; that the character of these materials and the quality of the concrete made with the specified proportions of these ingredients will be determined by careful tests; and that the coarse aggregate shall consist of sound, hard stone or gravel having a coefficient of wear of not less than ten for one-course construction and for the wearing course of two-course construction; and not less than seven for the base of two-course construction.

One-Course Concrete.—For a one-course concrete pavement the materials should be mixed in the proportion of one sack of Portland cement, two cubic feet of fine aggregate, and three cubic feet of coarse aggregate; and a cubic yard of the resulting concrete in place should contain not fewer than six and eight-tenths sacks of cement.

Two-Course Concrete.—For the base of a two-course pavement the materials should be mixed in the proportion of one sack of Portland cement, two and one-half cubic feet of fine aggregate, and five cubic feet of coarse aggregate; and a cubic yard of the resulting concrete in place should contain not fewer than five and six-tenths sacks of cement.

If the base is to consist of cement and fine aggregate the material should be mixed in the proportions of one sack of Portland cement to not more than four cubic feet of fine aggregate; and a cubic yard of the resulting concrete in place should contain not fewer than eight and two-tenths sacks of cement.

For the wearing course of a two-course pavement the materials should be mixed in the proportion of one sack of Portland cement to not more than two cubic feet of fine aggregate; and a cubic yard of the resulting concrete in place should contain not fewer than eleven and eight-tenths sacks of cement.

Whenever it is economical to do so the materials in the wearing course should be mixed in the proportions of one sack of Portland cement, one and one-half cubic feet of fine aggregate, and two and one-half cubic feet of coarse aggregate which would be retained on a quarter inch mesh sieve and which would pass a three-quarter inch mesh screen, in order to reduce the difference between the expansion and contraction in the base and wearing courses to a minimum.

Hydrated Lime.—Many experiments in concrete road construction have been made recently with hydrated lime added to the concrete in amounts ranging from five to ten per cent. by weight of the cement. Information available at the present time seems to indicate that the addition of a small percentage of some inert material such as hydrated lime may be of value in concrete road construction for it decreases the percentage of voids and produces a more impervious concrete, and reduces the expansion and contraction under moisture changes; but at this time your committee does not feel warranted in making any definite recommendations.

Consistency of Concrete

The terms used in defining the proper consistency of concrete are generally indefinite and to one man may mean one thing and to another something else. The following examples taken from the replies to the inquiries sent out are representative of the present practice:

"Plastic."

"Plastic enough to retain its shape when screeded, and not to be so plastic that a flow of mortar will be produced on the top, or in which any segregation can take place."

"Mixture must be plastic and of such consistency that it can be troweled and will quake slightly under the trowel."

"Concrete wet enough so that it can be worked easily, yet dry enough to retain its shape—a quaking mixture."

"A quaking mixture that can be made even by tamping."

"A quaking mixture which can be struck off with template."

"Like thick cream."

"Such that a light tamping will bring mortar to the surface."

"Wet enough to produce a concrete that will flush readily under light tamping."

"Dry enough to require slight tamping to settle into place."

"Wet enough to settle in flat mass but not to run on subgrade."

"Works easily under template."

"Requires use of hoe to keep concrete moving."

"Wet enough to flow into place with assistance of laborers and work easily under template."

"A concrete which will hold its shape when struck off with a template."

"Holds its shape when struck with template, but such that the materials will not separate."

"A consistency such that concrete can be conveyed and deposited without separation of coarse aggregate from the mortar."

"No excess water to appear after a thorough tamping."

"Consistency such that when walked onto the foot is removed with effort and the remaining hole does not run full of mortar."

Amount of Water

The amount of water necessary to produce the required consistency varies from about six to twelve per cent. by weight, or from fourteen to thirty per cent. by volume of concrete, and from eighteen to thirty-five gallons, or from one hundred and fifty to three hundred pounds per cubic yard of concrete. This great variation is largely due to: the amount of moisture in the aggregates, the character of the materials, and the atmospheric conditions.

Requirements for consistency should be specified in a more definite way than is usual. It is evident, however, that a standard consistency cannot be expressed in terms of the percentage of water used.

The required consistency can probably be expressed in the most satisfactory terms by describing how the concrete acts and the form it takes when thoroughly mixed and deposited on the subgrade. From this it would seem that some laboratory consistency requirements might be worked out; and it is recommended that extensive investigations be made to devise apparatus and a method of testing concrete which may result in establishing some standard consistency. Until such an investigation is made little can be done to overcome the present unsatisfactory consistency specifications.

The objections to mixing concrete too wet should be especially emphasized. There is practically no danger of having the concrete mixed too dry for the workmen soon learn that by using an excess of water the concrete can be mixed with less effort, and handled, placed and finished more readily than when it is of the proper consistency, and this partly accounts for the general practice of mixing concrete for road work too wet.

It is a matter of general observation both in the field and the laboratory that with the same materials, other things being equal, a wet mixture is inferior in quality and strength to concrete of a medium or quaking consistency. The information available to date also indicates that the expansion and contraction of concrete may be materially affected by the amount of water used in the mixing.

Wet, slushy concrete has the further disadvantage of bringing to the surface any small pieces of wood, bark or other light perishable material that may have gotten into the aggregate. This causes unsightly pitting of the surface and necessitates immediate repairs.

The consistency of concrete for road or street work should be such that when deposited from a chute or bucket it will settle in a flat mass, but will not flow on the subgrade. No tamping should be required and no separation of the mortar from the coarse aggregate should occur in handling the concrete or in finishing the surface.

Handsome New Buildings in Montreal

By E. F. Dartnell*

IN Montreal and the immediate vicinity there are many fine buildings either under construction, or just recently completed which are a credit to Canada's largest city. The following are typical.

The new High School on upper University street, completed during 1914 and illustrated as Fig. 1. The building is trimmed with Indiana Limestone and faced with light grey Kittanning vitrified brick of Norman size, these lend themselves remarkably well to the design of the building and show conclusively that excellent artistic effects can be produced by the use of a smooth brick of the one shade, provided the architect bears in mind the texture and color of his material, getting his tones altogether from the light and shade, which has been very successfully carried out in this case. Architects, Messrs. E. & W. S. Maxwell; general contractors, the Geo. A. Fuller Co., Limited.

Almost opposite to the High School, but a little further up the street, is the Wesleyan Theological College, Fig. 2, a handsome building faced with grey, rough textured Caledonian brick, in mingled shades, laid up in Flemish bond. Architects, Messrs. Ross & Macdonald; general contractors, C. E. Deakin, Limited.

The new Southam Office Building, Fig. 3, on Bleury street, recently completed, is a striking, well

* President, Dartnell, Limited, Montreal.

Fig. 1—Montreal High School, University Street, Montreal.

Fig. 2—Wesleyan Theological College, University Street, Montreal.

designed structure, faced with grey Caledonian brick, similar to those used in the Wesleyan College, with white terra cotta trim. Architects, Messrs. D. R. Brown & Hugh Vallance; general contractors, the Atlas Construction Co., Limited.

The Roman Catholic parish of St. Arsene, has recently completed a Presbytery at the corner of Christopher Columbus and Daniel streets, this is faced with a light grey, rough Caledonian brick. Architect, Mr. Zotique Trudel; contractor for brickwork, Mr. Paul Labelle.

The Civic Library at the corner of Montcalm and Sherbrooke (East) streets is shown in Fig. 4. Architect, Mr. Eugene Payette; contractors, Messrs. John Quinlan & Co. This is a very handsome structure. The front is of stone from Queenston, Ont., with a white Kittanning vitrified brick for facings of the rear wings of building.

The Customs Examining Warehouse, on McGill street, built of Nova Scotia sandstone of a light color, is a large and handsome building. In the interior the lining is all of dry pressed buff brick, about a half million of which were supplied from the work of the Toronto Pressed Brick & Terra Cotta Co., of Milton, Ont., for the purpose. The building was designed by the chief architect of the Department of Public Works, Ottawa, with Mr. A. H. Lapierre, of Montreal, as associate architect. The P. Lyall & Sons Construction Co., Ltd., were general contractors. It is the intention of the government, in the near future, to extend the building north along McGill street to Youville square, making the building when completed fully double the size of the present section, and thus have the custom house and examining warehouse under the one roof. This will be a great convenience to those of the public who have business to transact with the

Fig. 3 The Southam Building, Bleury St.

Fig. 4—Montreal Civic Library, Corner of Montcalm and East Sherbrooke.

Customs, as at present the two departments are some distance apart.

The new home for Loyola College, at Notre Dame de Grace, is a handsome group of buildings from the design of Architect W. J. Murray, with whom Messrs. Peden & McLaren are associated. The buildings are faced with a rough textured brick of a reddish-brown

Fig. 5—Residence of J. S. Archibald, Architect, Corner of W. Dorchester St. and Bruce Ave.

color, in many shades, laid up with a wide, white mortar joint. The buildings are situated to the north of the C. P. R. tracks, between Montreal West and Westmount, and will be a conspicuous feature in the landscape. The general contractors are Messrs. Anglins, Limited. A handsome radial buff chimney, erected by H. R. Heinicke, Inc., is included in this group.

In the same neighborhood, but nearer to the city, on Decarie Boulevard, is a Catholic Orphanage from the plans of Mr. Alphonse Piche, architect, with the Deakin Construction Co., Ltd., as general contractors. This will be a prominent building, built of grey Caledonian brick of rough texture.

Mr. J. S. Archibald, of the architectural firm of Saxe & Archibald, has erected a handsome dwelling for himself at the corner of Dorchester West and Bruce streets, Fig. 5. This is of red "Tapestry" brick.

The Sun Life Assurance Co.'s large and imposing office building is built of Granite, with rear walls of grey Kittanning brick. It is situated on the East side of Dominion square, facing the Windsor Hotel. Architects, Darling & Pearson, Toronto; contractors, the P. Lyall & Sons Construction Co., Limited.

The new home of the Liverpool, London & Globe Insurance Co., at the corner of Dorchester street West and Union Avenue is a fine, handsome structure of grey Ohio sandstone. Architects, Messrs. Nobbs & Hyde and Mr. J. Rawson Gardiner, contractors, Messrs. E. G. M. Cape & Co., Limited.

The Royal Victoria Hospital are erecting another large building, which they have been enabled to do through the late Mr. James Ross, who left them a legacy of a half million dollars for the building and equipment of same. Architects, Messrs. Stevens & Lee, with Mr. Kenneth G. Rea, associate; contractors, Messrs. E. G. M. Cape & Co., Limited.

St. Michael's Church at the corner of St. Viateur and St. Urbain Streets, now in course of erection, will be a handsome building, a dull red brick in many shades and of rough texture is being used. This will be one of the first of large Catholic Churches to be built of brick in this Province. Architect, Mr. Beaugrand-Champagne; contractors, The Atlas Construction Co., Limited.

Mineral Production of Canada, 1915

Output of mines largest on record—Ontario stands highest in value 44% of total — British Columbia shows biggest per cent. increase

The following extracts are taken from the annual preliminary report on "The Mineral Production of Canada in 1915" prepared by John McLeish, B.A., Chief of the Division of Mineral Resources and Statistics. The figures for production in 1915, while subject to revision, are based upon direct returns from mine and smelter operators and are fairly complete.

Effect of the War

As a result of the demand created by the war, the metal mining industry has, in 1915, shown the highest production ever recorded and notwithstanding the greatly decreased production of materials of construction, such as cement, clay and stone quarry products, a very large increase is still shown in the total mineral output, over that of the previous year.

The total value of the metal and mineral production in 1915, as shown in the preliminary report presented herein, Table I, was $138,513,750, compared with $128,863,075 in 1914, and $145,634,812 in 1913, the latter being the highest production recorded. The increase in 1915 over 1914 was thus $9,650,675, or 7.49 per cent. but the output is still less than that in 1913 by $7,121,062.

TABLE I.

THE MINERAL PRODUCTION OF CANADA IN 1915.

Without attempting to discuss at length the effect of the war upon the Canadian mining industry, it may be remarked that the demand for the metals, copper, lead, nickel and zinc, led to great activity in the operation of the already developed deposits of these metals, and also, later in the year, to the opening up of old and the exploitation of new deposits. The capacities of steel furnaces were taxed to the utmost to meet the demand for shell steel.

The fact that under war conditions it was desirable that our metals should become available for commercial or national use, entirely within the country and that we should be less dependent, even upon a friendly neutral, for their recovery in smelters and refineries has stimulated the development of our smelting and refining operations.

Amongst non-metallic minerals the recovery of benzol and toluol in by-product coke oven operations was a direct result of the war, as was also the activity in the mining and shipment of magnesite and of chrome ores.

Increase or Decrease in Principal Products, 1915

It will be seen from Table II that there has been an increased production in all metals with the exception of silver. The total value of the metallic production in 1915 was $77,046,082 as compared with $59,386,619 in 1914, and $66,361,351 in 1913, the increase

over 1914 being nearly 30 per cent., and that over 1913 the highest previous year, about 16 per cent. The production of nickel, copper and zinc are the highest that have been recorded in these metals. The quantity of nickel was 50 per cent. greater than in 1914, copper over 35 per cent. greater, lead nearly 25 per cent. greater, gold over 18 per cent. and pig iron nearly 17 per cent. The falling off in silver was only 48,000 ounces or less than two-tenths of one per cent. Owing to the high prices of copper and lead the total values of these metals show increases of 72 per cent. and 56 per cent. respectively.

Compared with 1914 the average price of copper shows an increase of 27 per cent., lead an increase of 27 per cent., spelter an increase of 154 per cent., antimony (ordinaries) an increase of 246 per cent., silver a decrease of 9.4 per cent. and tin an increase of 12.2 per cent.

Metal Prices

The total value of the non-metallic production in 1915 including clay and quarry products, etc., was $61,467,668 as against $69,476,456 in 1914; $79,273,461 in 1913. Compared with 1914 the decrease was $8,008,788, or 11.5 per cent., while compared with 1913 the falling off was $17,805,793 or 22.5 per cent.

It will be seen that the largest decreases in 1915 occurred in materials of construction such as cement, clay products, lime, sand and gravel, and stone and quarry products, the falling off varying from 16 to nearly 34 per cent. There was, however, also a smaller production of coal, natural gas and gypsum. On the other hand there were increases in the shipments of asbestos, chromite, graphite magnesite, pyrites and salt.

*Quotations furnished by Messrs. Thomas Robertson & Company, Montreal, Que.

Ontario again has the largest output with a value of $61,800,178, or 44.6 per cent. of the total, and showing an increase over 1914 of $8,765,501, or 16.5 per cent. British Columbia occupies second place with a value of $28,932,658, or 20.9 per cent. of the total and showing an increase of $4,768,619, or 19.7 per cent. over 1914; Nova Scotia is third with a production valued at $18,126,672, or 13.1 per cent. of the total and showing an increase of $542,033, or 3.1 per cent. over 1914. Quebec comes fourth with a value of $12,159,436, or 8.8 per cent. of the total, and an increase over 1914 of $322,507, or 2.7 per cent. Alberta occupies fifth place with a production of $9,915,282, or 7.2 per cent. of the total and showing a decrease of $2,768,952, or 21.8 per cent. compared with 1914. The Yukon district mineral production including copper and coal as well as gold, is sixth, with a value of $4,915,863, or 3.6 per cent. of the total and a falling off from 1914 of $502,322, or 9.3 per cent. Manitoba's production was $1,351,604, a falling off of $1,061,885, or 44 per cent. New Brunswick's production was $916,329, a decrease of $98,241, or 9.7 per cent. and the production of Saskatchewan was the smallest, being $395,728, or less than that of 1914 by $316,585, or 44.4 per cent.

Gold

The total production of gold in placer and mill bullion and in smelter products in 1915 is estimated at 916,076 fine ounces valued at $18,936,971, as compared with 773,178 fine ounces valued at $15,983,007 in 1914, an increase of $2,953,964 or 18.5 per cent. Although the production has more than doubled since 1907 it has not yet reached the high mark attained during Klondike's best years.

Of the total production in 1915 about $5,550,987 was derived from placer and alluvial mining, $9,195,307 in bullion and refined gold and $4,230,677 contained in matte, blister copper, residues and ores exported.

The production in Nova Scotia was about $137,178, or over twice the output of the previous year. The pyrites ores of Quebec carry small quantities of gold and silver though the producers are not paid therefor. No placer recovery was reported from this province.

Ontario has now become the largest gold-producing province in Canada, the production in 1915 from fifteen properties being reported as $8,386,956, or 44 per cent. of the total production in Canada, as against a production in 1914 of $5,545,509 an increase of $2,841,447, or 51 per cent. The Hollinger and Acme Mines contributed about one-half of the output in 1915 and the Dome nearly one-fifth of the total.

The exports of gold bearing dust, nuggets, gold in ore, etc., in 1915 are reported by the Customs Department at $16,528,143.

Silver

The production of silver was 28,401,735 ounces valued at $14,088,397 as against 28,449,821 ounces in 1914, valued at $15,593,630. Silver is the principal metal that did not show an increased production in 1915. The falling off in quantity was very small however amounting to only 48,086 ounces. Owing to the lower price of silver the decrease in total value was $1,505,234 or over 9.6 per cent.

Of the total production in 1915, 24,653,057 ounces, or about 86.8 per cent. is credited to Ontario.

The exports of silver bullion and silver in ore, etc., as reported by the Customs Department, were:— 27,672,481 ounces valued at $13,812,038.

The price of silver in New York varied between a minimum of 46¼ cents in September and a maximum of 56 cents in December, averaging for the year 49.684 cents, a decrease of 5.127 cents from the average price in 1914.

Copper

The copper output in 1915 was the highest recorded. The production in smelters together with the estimated recoveries or amounts paid for in ores exported amounted to 102,612,486 pounds which at the average New York value of refined copper would be worth $17,726,307. The highest previous production was in 1912 when an output of 77,832,127 pounds was reached. Compared with the production in 1914 which was 75,735,960 pounds valued at $10,301,606 an increase is shown of 26,876,526 pounds or 35 per cent. and in total value of $7,424,701, or 72 per cent.

TABLE IV.

Mineral Production by Provinces, 1914 and 1915.

	1914		1915.		Increase (+) or Decrease (−).

The New York price of electrolytic copper rose from a minimum of 13 cents per pound in January to 20 cents in June, falling again to 16 cents in August, then rising steadily to the end of the year, reaching a maximum of 22 cents at the end of December. The average monthly price for the year was 17.275 cents, as compared with an average of 13.602 cents in 1914, an increase of 3.673 cents, or 27 per cent. This is the highest average monthly price since 1907, when 20.004 cents per pound was reached.

Exports of copper according to Customs records were; copper fine in ore, etc., and copper in pigs 102,729,579 pounds valued at $12,460,356, there were also exports of old and scrap copper amounting to 4,161,600 pounds valued at $616,553.

The total value of the imports of copper in 1915 are recorded as $3,467,586 as against $4,256,901 in 1914. The imports in 1915 included 16,818,116 pounds of copper in pigs, ingots and manufactures, valued at $3,104,382; other manufactures valued at $263,922, and copper sulphate 1,854,850 pounds, valued at $99,282.

The imports in 1914 included 26,280,815 pounds crude and manufactured copper valued at $3,983,322, copper sulphate 1,143,039 pounds valued at $53,802 and other manufactures of copper valued at $219,777.

Nickel

Refined metallic nickel is now being recovered in Canadian refineries but only in small quantities and as a by-product in the smelting and refining of the silver-cobalt-nickel ores of the Cobalt district, nickel oxide having been recovered in these smelters for several years. The nickel-copper ores of the Sudbury district supplemented by a small tonnage of similar ores from the Alexo mine in Timiskaming, north of Cobalt are the main sources of nickel production which in 1915 increased nearly 50 per cent. as compared with 1914 and is greater than the production in 1913, the largest previous record, by over 37 per cent.

TABLE V.

* In tons of 2,000 lbs. (a) Eleven months only.

The exports of nickel are reported by the Customs Department as 66,410,400 pounds valued at $7,394,446 or an average of 11.13 cents per pound. Since about 80 per cent. of the Canadian nickel production is exported to the United States, it may be of interest to add to the Canadian statistics a record of the imports (eleven months only in 1915) of nickel into and the exports from the United States.

The exports of nickel from the United States during the eleven months ending November were 24,503,585 pounds valued at $9,299,234 or an average of 37.95 cents per pound. More than 50 per cent. of these exports went to the United Kingdom. The value of the United States exports in 1914 ranged from 31 to 39 cents per pound and averaged about 34 cents.

It will be noted that a larger quantity of nickel finds its way to the United Kingdom through United State's refineries than is exported directly from Canada.

The price of refined nickel in New York remained fairly constant during the first seven months of the year, quotations published by the Engineering and Mining Journal being 40 to 45 cents per pound for ordinary forms with 5 cents per pound more asked for electrolytic metal. During the last five months of the year prices ranged between 45 and 50 cents for ordinary forms.

Lead

Although there was an increase of nearly 25 per cent. in the production of lead the 1915 output has been exceeded in six of the past 15 years. The production of lead in 1915 was 45,377,065 pounds, which valued at 5.60 cents per pound, the average price of pig lead in Montreal for the year, would be worth $2,541,116. The production in 1914 was 36,337,765 pounds valued at $1,627,568, or an average of 4.479 cents per pound. The 1915 production consists chiefly of pig and manufactured lead produced at Trail, B. C., but includes also an estimate of the lead probably recoverable from ores shipped to smelters outside of Canada. The entire output of the Surprise mine in the Slocan District, B. C., was shipped to the United States, refined in bond, and sold in London.

The exports of lead in ore, etc., in 1915 are recorded by the Customs Department as 1,845,100 pounds valued at $40,273, and of pig lead 2,066,929 pounds valued at $79,067. Exports in 1914 were 246,100 pounds of lead in ore and 510,573 pounds of pig lead.

The total value of the imports of lead and lead products in 1915 was $2,479,261 as against $1,042,538 in 1914.

The average monthly price of lead in Montreal varied between a minimum of 4.27 cents in January and a maximum of 6.61 cents in December, averaging for the year 5.60 cents.

The average monthly price of lead in New York was 4.628 cents and in London £22.917 per gross ton, equivalent to 4.979 cents per pound.

Zinc

Complete returns of zinc shipments have not yet been received but the tonnage is estimated at 15,553 tons containing 12,400,000 pounds of zinc. Shipments include several hundred tons from Notre Dame des Anges, Quebec, but the greater part is from fifteen properties in British Columbia. Zinc shipments in 1914 were reported as 10,893 tons containing 9,101,460 pounds of zinc.

The price of spelter in New York varied between a minimum of 5¾ cents per pound in January and a maximum of 25 to 27 cents in June, the price at the close of the year being from 15¼ to 16¾ cents and the average for the year 13.230 cents per pound.

The price of high-grade spelter rose from 10 cents at the beginning of the year to over 40 cents in midsummer and was maintained fairly strongly through the balance of the year at from 35 to 40 cents.

Antimony

After several years of no production the demand and high prices in 1915 caused a renewal of activity in mining antimony ores at West Gore, Nova Scotia, and Lake George, New Brunswick. About 1,288 tons of concentrates were shipped to England from the former locality. The total production reported is estimated at about 961,040 pounds of antimony refined and in concentrates.

The recorded exports of antimony ore in 1915 were 1,149 tons valued at $82,990, while the imports included antimony or regulus of, etc., 1,962,194 pounds valued at $344,918 and antimony salts 67,956 pounds valued at $10,320.

The price of antimony, ordinary grades, in New York ranged between a minimum of 13 cents in January to a maximum of 42 cents in December, averaging about 30 cents for the year.

Cobalt

Metallic cobalt is now being recovered as well as cobalt oxide at the smelters at Deloro and Thorold. The silver-cobalt-nickel ores of the Cobalt district are reduced in these smelters, silver being the principal product with arsenious oxide, metallic cobalt and nickel, cobalt oxide and nickel oxide as by-products. Returns received showed a production in 1915 of 211,610 pounds of metallic cobalt and 379,219 pounds of cobalt oxide, equivalent to a total of 477,063 pounds of metal. In 1914 the production was reported as 899,027 pounds of cobalt oxide and 242,572 pounds of cobalt contained in residues sold outside of Canada or equivalent to a total of 871,891 pounds of cobalt.

Molybdenum

A production has been reported of about 28,600 pounds of molybdenite valued at $28,460, including cobbed molybdenite and molybdenite contained in ore shipped to concentration plants. There were also about 50 tons of low-grade ore sent to the Mines Branch Ore Testing laboratories for experimental concentration.

Platinum

Efforts are being continued to recover platinum from the gravels on the Tulameen river in the Similkameen district of British Columbia and there is also occasional recovery of small quantities from the gold gravels of Quesnel division, Cariboo district. A recovery of about 20 ounces is reported in 1915. There was no recovery of platinum from the Sudbury nickel-copper mattes.

Customs records show an export of platinum of 236 ounces valued at $11,052, but this may possibly include old metal.

The price of refined platinum in New York which was about $41 per ounce in January fell to $38 in June and July, but increased to an average of $85.50 in December. The year's average was about $47.

Iron Ore

Iron ore shipments in 1915 amounted to 398,112 short tons valued at $774,427 as compared with 1914 shipments of 244,854 short tons valued at $542,041.

Mine operators report 93,444 tons of ore exported to the United States and 304,668 tons shipped to Canadian furnaces.

According to the records of the Customs Department exports of iron ore amounted to 79,770 tons valued at $206,823 and imports of iron ore to 1,499,722 tons valued at $2,320,066.

Pig Iron

The total production of pig iron in Canadian blast furnaces in 1915 was 913,719 short tons, valued at approximately $11,592,819 as compared with a production of 783,164 short tons in 1914 valued at approximately $10,002,856. The 1915 output shows an increase of 130,555 tons or 16.67 per cent. over that of 1914, and compares favorably with the average of recent years.

Of the total production in 1915, 13,692 tons were made with charcoal and 900,027 tons with coke.

Included in the ore charged to blast furnaces there was 293,305 short tons from Canadian mines and 1,463,681 tons of imported ore. Of the imported ore naces of 10,794 tons of ferro-alloys (chiefly ferro-sili-

There was also in 1915 a production in electric furnaces of 10,794 tons of ferro-alloys chiefly ferro-silicon with a very small tonnage of ferro-phosphorus) valued at $753,406 as compared with a production in 1914 of 7,524 tons valued at $478,355.

The exports during 1915 of pig iron were 17,307 short tons valued at $231,551 or an average per ton of $13.38, and of ferro-silicon and ferro-compounds 9,238 tons valued at $537,081, an average of $50.81 per ton, or a total of 26,545 tons valued at $768,632 as compared with a total in 1914 of 19,063 tons valued at $486,366. The imports were 47,482 tons of pig iron valued at $624,200, or an average of $13.15 per ton, and 13,758 tons of speigeleisen, ferro manganese and ferro-silicon valued at $807,312, or a total of 61,240 tons valued at $1,431,512.

Steel Ingots and Castings

The production of steel ingots and castings in 1915 including 5,626 tons from electric furnaces, was 1,020,335 short tons, as compared with a production in 1914 of 828,641 tons. The 1914 production included open-hearth ingots 608,383 tons; bessemer ingots 203,184 tons; direct open-hearth castings 15,315 tons; and other steel castings 1,759 tons.

Asbestos

The asbestos production in 1915 was obtained from the same field in Quebec as heretofore. The output was less than in 1914, but sales showed an increase of about 17 per cent. Stocks on hand at the end of the year showed a noticeable decrease.

The total output in 1915 was 106,558 tons, as against 107,668 tons in 1914, showing a decrease of 1,110 tons or 1.03 per cent. The sales and shipments during 1915 were 113,115 tons valued at $3,491,450, or an average of $30.87 per ton, as against sales in 1914 of 96,542 tons valued at $2,892,266 or an average of $29.92 per ton. The total sales were larger in quantity than those of 1914 by about 17 per cent. and in value by about 20 per cent.

Exports of asbestos during the calendar year 1915 were 84,584 tons valued at $2,734,695 or an average of $32.45 per ton, as against exports of 81,081 tons in 1914 valued at $2,298,646 or an average of $28.35 per ton. There was also an export of asbestos sand amounting to 25,103 tons valued at $157,410 or an average of $6.27 per ton and of manufactures of asbestos valued at $125,003.

Imports of asbestos manufactures for the year amounted to $168,894.

Coal

The total production of marketable coal for the year 1915 (comprising sales and shipments, colliery consumption, and coal used in making coke, or used otherwise by colliery operators), was 13,209,371 short tons valued at $31,957,757, as against 13,637,529 tons valued at $33,471,801 in 1914 showing a decrease of 428,158 tons, or 3.14 per cent. in quantity, and of $1,514,044 or 4.52 per cent. in total value.

The exports of coal in 1915 were 1,766,543 tons valued at $5,406,058 as compared with exports of 1,423,126 tons in 1914 valued at $3,880,175, an increase of 343,417 tons or 2.41 per cent.

The imports of coal in 1915 were made up as follows: bituminous round and run of mine: 6,106,794 tons, valued at $7,564,369, or an average of $1.24 per ton, bituminous slack 2,286,916 tons valued at $2,027,256, or an average of $0.89 per ton, and anthracite 4,072,192 tons valued at $18,753,980 or an average of $4.61 per ton, making a total of 12,465,902 tons valued at $28,345,605.

The apparent consumption of coal during 1915 was 23,849,040 tons, as against a consumption of the previous year of 26,852,323 tons. Canadian mines contributed 48 per cent. of the domestic consumption, and the balance was imported. The total Canadian production was equivalent to about 53.4 per cent. of the consumption.

Coke

The output of oven coke during 1915 was 1,200,766 short tons made from 1,856,393 tons of coal of which 1,425,172 tons were of domestic origin, and 431,221 tons were imported. The total quantity of coke sold, or used by the producers during the year was 1,168,921 tons valued at $4,253,536 or an average of $3.64 per ton.

In 1914 the total output was 1,015,253 tons, and the quantity sold, or used by the producers, was 1,023,860 tons valued at 3,658,514 or an average of $3.57 per ton.

By-products from coke ovens which included 10,448 tons of ammonium sulphate, 7,365,931 gallons of tar, and 4,089,602 thousand cubic feet of gas, made in 1915 were in excess of the production in 1914; there was also for the first time a production of benzol and associated compounds. The production of trinitrotoluene near the close of the year was reported by Col. Carnegie of the Shell Committee, as 110,000 pounds per week.

Imports of coke during 1915 amounted to 637,857 tons valued at $1,608,464, and exports were 35,869 tons valued at $160,053.

Other Non-Metals

Graphite: Shipments of milled and refined graphite amounted to 2,610 tons valued at $121,023 or an average of $46.37 per ton. The 1914 production was 1,647 tons valued at $107,203. Operators report a greatly increased demand with higher prices owing to the shortage in supplies in the United States from sources outside of America.

Gypsum: The production of gypsum of all grades in 1915 is reported as 470,335 tons valued at $849,928. This is lower than for several years, previous production having been 516,880 tons in 1914; 636,370 tons in 1913; and 578,454 tons in 1913.

Exports of crude gypsum were 292,234 tons valued at $336,380 being the smallest reported since 1908. Exports of ground gypsum which were valued at less than $10,000 yearly for many years rose to a value of $35,490 in 1914 and to a value of $80,933 in 1915.

Magnesite: The production of magnesite in 1915, chiefly crude but including some calcined, was 14,779 tons valued at $126,535 in contrast with a yearly average production from 1908 to 1914 inclusive of 621½ tons. The increased production was due largely to the urgent demands of steel companies and manufacturers of refractory brick.

Manganese Ores: In 1915 there was according to returns received to date, a production of 47 tons of manganese ore (90 per cent. MnO_2) valued at $5,460 or an average of $116.17 per ton, as compared with a production in 1914 of 28 tons, valued at $1,120 or an average of $40.00 per ton.

The records of the Customs Department show exports of manganese ores amounting to 255 tons, valued at $6,855, which would seem to indicate shipments additional to those reported.

Natural Gas: The 1915 production of natural gas was approximately 18,319,710 thousand cubic feet valued at $3,300,825.

The production of the previous year was reported as 21,692,504 thousand cubic feet valued at $3,484,727.

Pyrites

The production of pyrites in 1915 was 296,910 tons valued at $1,028,678. The 1914 production was 228,314 tons valued at $744,508.

Exports of pyrites in 1915 were 137,598 tons valued at $527,318, or an average of $3.83 per ton, as compared with exports in 1914 of 89,888 tons valued at $377,985, or an average of $4.21 per ton.

Cement

The general decrease in production of structural materials and clay products which was a feature in 1914 was repeated in 1915, the production in the latter year being valued at $18,712,074, as against a production in 1914 valued at $26,009,227.

The total quantity of Portland cement, including natural Portland, made in 1915 was 5,153,763 barrels of 350 pounds each, as compared with 8,727,269 barrels in 1914, a decrease of 3,563,506 barrels, or about 40 per cent.

TABLE VI.

Production and Sales of Portland Cement.

	1912.	1913	1914.	1915
	Brls.	Brls.	Brls.	Brls.
Portland Cement sold or used	7,132,732	8,658,805	7,172,480	5,681,032
" manufactured	7,141,404	8,886,333	8,727,269	5,153,763
Stock on hand Jan. 1st	894,822	862,067	1,073,328	2,620,022
" Dec. 31st	903,094	1,089,595	2,628,117	2,062,961
Value of cement sold or used	$ 9,106,556	$11,019,418	$ 9,187,924	$6,977,024

Consumption of Portland Cement.

Calendar Year.	Canadian.		Imported.		Total.
	Barrels.	Per cent.	Barrels.	Per cent.	Barrels.
1911	5,692,915	90 0	661,916	10.0	6,354,831
1912	7,132,732	83·3	434,413	16·7	8,567 145
1915	8,658,805	97·1	254,093	2·9	8,912,988
1914	7,172,480	98·7	98,022	1·3	7,270 502
1915	5,681,032	99·5	28,190	0·5	5,709,222

The total quantity of Canadian Portland cement sold or used during 1915 was 5,681,032 barrels, valued at $6,977,024 or an average of $1.228 per barrel, as compared with 7,172,480 barrels, sold or used in 1914, valued at $9,187,924, or an average of $1.28, showing a decrease in quantity of 1,491,448 barrels, or about 20 per cent.

The total imports of cement in 1915 were 98,664 cwt. equivalent to 28,190 barrels of 350 pounds each, valued at $40,426, or an average of $1.434 per barrel, as compared with imports of $98,022 barrels, valued at $147,158, or an average of $1.50 per barrel in 1914.

The total consumption of cement, therefore, neglecting a small export, was 5,709,222 barrels, as compared with a consumption of 7,270,502 barrels in 1914, showing a decrease of 1,561,280 barrels, or about 21 per cent.

The average price per barrel at the works in 1915 was $1.228 as compared with $1.28 in 1914, $1.27 in 1913, $1.28 in 1912, and $1.34 during 1911 and 1910.

The imports of cement in 1915 included 1,065 barrels, valued at $1,480 from Great Britain, and 27,125 barrels, valued at $38,946, from the United States.

Welland and Georgian Bay Canals

Economic and Strategic Aspects of Enlargement of Welland Canal and Construction of Georgian Bay Canal

By R. W. Leonard, M. C. S. C. E.*

This is a most important subject for debate by the Canadian Society of Civil Engineers, because it involves vitally the probability of continued existence of our international boundary, as well as the question of the economic expenditure of vast sums of money, and because it is a question that should be solved by civil engineers.

Internationally, the question involves the use of constricted water-ways at Sault Ste. Marie, St. Clair River, Detroit River, Welland Canal and St. Lawrence River by both peoples, some of which water-ways are on one side of the boundary and some on the other, and the effect of such a condition in case of friction unhappily arising between Canada and the United States.

Commercially, the economics of the projects can be compared with transportation by rail and with one another. The expenditure involved and where it is spent, and the effect of the expenditure upon the country as a whole, are most important.

Civil engineers alone can make the surveys and determine the physical possibilities of construction, the cost of construction, and the relative engineering advantages or disadvantages in the construction, maintenance and operation, as compared with railway transportation on the one hand, and the one canal project with the other on the other hand.

This question is apparently of such wide scope, and involves technical detailed knowledge of so great variety that the writer submits it affords ground for much valuable discussion, which it is to be hoped will be elicited by this paper, contributed with diffidence but in good faith by the writer as his view.

Canal Systems

The present canal systems of commercial importance consists of:—

(1) Sault Ste. Marie Locks:—one on the Canadian side 900 ft. x 60 ft. x 19 ft. draft, one on the United States side 600 ft. x 100 ft. x 14 ft. draft, one on the United States sides 800 ft. x 100 ft. x 19 ft. draft, one on the United States side 1,250 ft. x 80 ft. x 24½ ft. draft, opened October 21, 1914, one on the United States side expected to be ready shortly

(2) Channels in United States territory below locks in Sault.

(3) Channels in Canada and United States in St. Clair River.

(4) Channels in Canada and United States in Detroit River.

(5) Welland Canal, including 24 locks, 270 ft. x 45 ft. x 14 ft. draft.

(6) St. Lawrence canal system, 26 locks, 270 ft. x 45 ft. x 14 ft. draft.

After the War of 1812 the British Government recognizing the necessity of having a line of communication for military purposes away from the boundary—canalized the Ottawa River from Montreal to Ottawa, and the Rideau and Cataraqui Rivers from Ottawa to Kingston for barges drawing five feet of water at a cost of $3,911,700, which system they subsequently gave to Canada free of cost.

The Department of Railways and Canals has since nearly completed the Trent canal system from Trenton on Lake Ontario to Georgian Bay, for barges drawing about five feet of water at a cost to date (1914) of $13,611,035, exclusive of interest.

These last two systems—however interesting to the summer tourist as canoe and yachting routes—are not of great economic or strategic importance under modern conditions.

The cost, maintenance, operation and repairs for the year 1913 being $309,822.65, and the tonnage passing through (mainly pleasure boats, cord wood, lumber and sand) amounted to 227,023 tons.

Ottawa-French River Route

About 1904 the Dominion Government (Public Works Department) started a survey of the Ottawa-French River route for the purpose of arriving at the cost of a 22 ft. ship canal. The result is embodied in a very voluminous report, dated 1908, including estimates as follows:—

Total length of canal .... 440 miles, including:—	
Free navigation	346 miles
Improved channels	66 miles
Excavated canal	28 miles
Total	440 miles, 22 ft. deep.
Costing	$100,000,000.00

The system is estimated to be capable of developing 1,000,000 h.p. on the direct canal route, and this estimate might probably be doubled by figuring the power developed in regulating the tributary streams.

It is significant that about the same time the Department of Railways and Canals commenced to make surveys to determine the possibility of enlarging the Welland Canal from the present 14 ft. draft to 30 ft. draft. These surveys were completed in 1913 and the parliamentary estimate for that year included $2,000,000.00 for the enlargement of the Welland Canal and $500,000.00 for canalizing the French River from Georgian Bay to Lake Nipissing.

The total estimate of the cost of enlarging the Welland Canal (26 miles) is reported to be $50,000,000.00, probably two-thirds of which is expended in the United States for fuel and machinery, and in various foreign countries in the form of wages sent home by labourers.

The lift of 325 ft. is overcome by 7 locks of 46.5 ft. lift, 800 ft. long x 80 ft. wide x 30 ft. draft.

The St. Lawrence canals enlargement has not been surveyed and no information is therefore available to indicate whether corresponding enlargement to suit that at the Welland Canal is physically possible at any cost of construction, and the people of Canada have not been informed of any treaty with the United States sanctioning such deepening of international waters with the probable construction of international dams, etc.

During 1913-14 contracts were let for the construction of about ten miles of the Welland Ship Canal, in-

* Before Can. Soc. C. E., Montreal

cluding all the locks at a cost of probably $35,000,000.00 and the work of excavation is possibly half done.

Internationally considered, this question is of supreme national importance, as involving such questions as national defence and the very possibility of holding Canada for the Empire.

In this connection, it must be borne in mind that New York State is enlarging the Erie Canal from Troy to Oswego and to Buffalo, from six or seven feet draft to twelve feet with a lock length of 311 feet, and width of 45 feet, to accommodate barges of 1,500 tons capacity, these canals will open Lakes Ontario and Erie to formidable United States war vessels giving them absolute control of these lakes at all times, unless Canada be supplied with similar transport facilities apart from the boundary waters of the St. Lawrence River from Kingston to Prescott.

The enlargement of the Welland Canal will also carry a great preponderance of large United States steel freighters into Lake Ontario, thus giving to that country an undisputed control of that lake.

Canada has enjoyed a century of peace with her powerful southern neighbor, and it is the wish of all good citizens to enjoy another one, even avoiding in the coming century such incidents as the "Trent Affair," the Fenian Raids, Venezuela messages and the Panama canal question, and serious boundary disputes, fishery disputes, international water power questions, etc., to say nothing of United States Senate Reports, 1889-1890 (Testimony of Joseph Nimmo, Jr.), etc. Such questions having arisen in the past, however, they will naturally arise in the future, and the peaceful settlement of them depends largely upon the temper and temptations at the time. So long as an international boundary is to be retained, so long should the policy of Canada be to preserve peace while safeguarding her honor and interests.

Canada's Most Expensive Commercial Problem

It is not apparent to the public that this canal problem (probably Canada's most expensive commercial project under construction) has been considered by the Canadian people from the national point of view, though pamphlets have been published, ad nauseam, by Boards of Trade of various municipalities treating the subject in a spirit of parochial politics, each exaggerating the advantages of one route and the disadvantages of the other, the very apparent incentive in each case being the expenditure of public money on construction in the immediate vicinity of the municipalities interested.

If the question be approached from a purely economic point of view, it is probable that freight (and grain from the prairies to the Atlantic seaboard in Canada is the most important commodity at present) can most cheaply be handled by rail from Winnipeg to Fort William and Port Arthur, by ship to Georgian Bay, and by rail over a direct line with easy gradients to Montreal, than by any canal at present built or proposed. On this route the C. P. R. has a double track from the West to Fort William; the G. T. P. and the C. N. R. have each a single track between the same points. There is a large fleet of United States steamers engaged in the coal, grain and ore trade on the lakes, and the Canadian fleet is growing rapidly. The C. P. R. has a line with easy gradients from Port McNicoll, on Georgian Bay, where it has built large grain elevators, to connect with its Toronto-Montreal line, with a view to carrying grain in competition with the canals, and they probably have estimates of comparative cost warranting the expenditure, even under the unequal conditions that the traffic by the railway must pay interest, depreciation and upkeep, while the Government assumes these enormous sums in the case of the waterways making the canals free to all ships alike, Canadian and foreign.

Water Transportation Regulates Freight Rates

The people are educated to demand water transportation "to regulate rail freights," and to what extent a larger canal than the present 14-foot Welland-St. Lawrence system will result in a reduction of rates is a question that can be figured in many different ways with varying results. Figures have been prepared by competent authorities showing that the maximum saving in freight on wheat from Fort William to Montreal by the enlargement of the Welland Canal will be ⅜c. per bushel, which will amount to $187,500.00 per year on 50,000,000 bushels—at a cost in interest on $50,000,000.00 of say $2,000,000.00 per year plus depreciation, upkeep and operation.

Return cargoes of coal are obtained in Lake Erie ports. Probably few will contend that 14 ft. draft ships are not economical for package freight from Lake Ontario or St. Lawrence points.

It will be of interest in this connection to have a report on the feasability and cost from an engineering point of view of lengthening the existing locks on Welland and St. Lawrence canals 100 ft., and the economic results of such lengthening if it be practicable.

To analyse and compare the respective advantages and disadvantages of these two routes.

Assuming that the Government enlarges the Welland Canal and proposes to canalize the French River to North Bay only:

The estimate for the enlargement of the Welland is generally stated to be $50,000,000.00; which amount at 4 per cent. interest, together with amortization, upkeep and supervision of the two existing canals and the proposed canal, may be estimated at another $1,000,000.00, or a total of $3,000,000.00 per year, which sum is probably under the mark unless all past experience in cost of Government contracts be reversed.

Assuming the distance from Port McNicoll to Montreal to be 400 miles, and a paying freight rate to be four-tenths cents per ton mile, or $1.60 per ton, or 5c a bushel, then $3,000,000.00 per year would pay the rail freight from Georgian Bay to Montreal on 60,000,000 bushels, which is much greater than the amount of grain and flour shipped in the past from Montreal in any one year, and 50 per cent. greater than the greatest Canadian tonnage through the Welland Canal bound down in one year.

Water Rights

This enlargement of the Welland Canal will not materially increase the water power development, as that is regulated by international treaty and works out so that, though Canada owns two-thirds of the water flowing over Niagara Falls, she gets the use of only one-third of the power development therefrom, the United States getting two-thirds.

It is manifest that the only saving effected by enlarging the Welland will be that effected by the difference in freight rates between 2,000-ton ships from Port Colborne to Montreal vs. 8,000-ton ships from Port Colborne to Prescott, plus 2,000-ton ships from

Prescott to Montreal, estimated above at ⅜c per bushel on wheat.

Oswego is about 150 miles nearer (by Erie Canal) to Troy than is Buffalo, and, as the enlarged Welland Canal will be, by treaty, free to United States ships, their largest lake ships will deliver grain cargoes to 1,500-ton United States barges at Oswego, in the New York State Barge Canal for New York instead of into 200 or 300-ton barges at Buffalo as at present, and thus compete with large Canadian ships discharging into 2,000-ton barges at Prescott or Kingston for Montreal.

In the past the little Erie canal boats taking grain from Buffalo to New York have been very keen competitors against the St. Lawrence route. What will be the result of the new conditions when in operation? It would appear that the expenditure on the proposed Welland Canal enlargement when completed will be quite as much to the advantage of the United States as to Canada, and during construction probably much more than half the cost goes to the United States for coal and machinery.

Canalization of French River

The canalization of the French River to North Bay to a depth of 22 feet, a distance of 82½ miles, is estimated to cost $14,275,000.00, and would develop 35,000 h.p.

It could bring coal and coarse freight to North Bay for railway distribution, and return pulp-wood and probably ores from that district, and partially develop a lot of power for which there is probably no immediate market in sight, but the value of which will doubtless be very great in a few years if we judge from the phenomenal increase in the use and value of hydro-electric power during the past twenty years. Probably this construction is warranted only in anticipation of the completion of the entire canal to Montreal.

Assuming that the appropriations in the estimates for the Welland and French River works are preliminary to the extension of each system through to Montreal:

The Welland-St. Lawrence system (unless an entirely new route inland to the north of the St. Lawrence can be found) passes through international waters from Kingston to Cornwall, and probably nothing can be done toward enlarging this portion without international agreement, including a natural demand by the United States for a share of the power development (loosely estimated at 2,000,000 h.p. by some writers in the press.)

Would the United States, having the free use of the enlarged Welland to carry their big ships to Oswego (the end of their Erie canal) consent to the enlarging of the St. Lawrence system to divert the trade from Troy and New York to Montreal? What share of the expense would they bear? What share of the power developed would they demand?

Sufficient information is not available to indicate the nature or cost of such an enlargement of the St. Lawrence canals, to a depth of 22 feet.

Ottawa-French River System

In the case of the Ottawa-French River system, careful surveys and estimates have been made by the Public Works Department. The total length of the canal is 440 miles, of which 346 miles is free navigation, 66 miles in improved channels and 28 miles in excavated canal. The cost is estimated at $100,000,000.

The system is estimated to be capable of developing one million h.p. on the direct route and 3,000,000 h.p. including the tributaries which probably within twenty years will (if carefully conserved and utilized by the nation) be worth from twenty to one hundred dollars per year per horse power utilized over the cost of production from coal, depending upon the purpose for which it is used.

In the absence of authentic estimates and reports on the St. Lawrence route, it is impossible to compare the two routes as to practicability, cost, time of transit and economy of operation. It is not known whether the St. Lawrence enlargement is at all possible due to international questions. If it be possible, then the two systems can be compared in regard to length and total height of locking only.

From Lake Superior to Montreal the Ottawa route is 661 miles long, and the total lockage up and down is 780 feet.

The Welland-St. Lawrence route is 943 miles long, and the total lockage is 578 feet.

Both routes pass through United States waters in the St. Mary River. The St. Lawrence route passes through contracted international waters at St. Clair River, Detroit River and St. Lawrence River.

The deepened Welland-St. Lawrence Canal would be found to have probably three times the length of actual excavated canal and about the same length of restricted river navigation, as compared with the Ottawa route.

Much has been written about fogs, rock-excavated channels and sharp curves on the Ottawa route. Any Canadian knows that the St. Lawrence probably suffers quite as much as the Ottawa from fogs. About half of the existing Welland Canal is in rock excavation and the new canal will not have less. It is not known how much of such channels the proposed St. Lawrence enlargement will include. The Ottawa route has sharp curves, so has the Thames below London, and it is not known what curves will be required on the proposed St. Lawrence enlargement. There are, however, sharp curves in swift currents in St. Mary River at Neebish and other points.

Without surveys the distances through restricted waters cannot be compared and therefore neither the time necessary to pass through, nor the dangers of navigation.

The St. Lawrence route is known to be longer and will demand greater fuel consumption per ton of freight, and probably more time in transit.

The weeks per year when they will be open for navigation will probably not greatly differ, although the St. Lawrence system would doubtless have a slight advantage in this respect.

If, as shown above, the annual expense of enlarging the Welland Canal alone would pay the freight on double the quantity of wheat and flour at present carried per year from Lake Huron to Montreal, it is unnecessary to prove that (commercially speaking) neither scheme can be defended as a canal solely. Without further information they cannot be compared physically, nor is the possibility of the St. Lawrence enlargement even sure.

Conclusion

Pending the result of discussion the writer cannot avoid the following conclusions:—

(a) Neither canal system can be made, as a canal, a commercial success;

(b) On account of the geographical position and abundance of power capable of being developed along the Ottawa-French River system, that canal and power development (if undertaken by the Government) can probably be made a commercial success in a few years and will be a very valuable asset in case of international disputes, giving Canada a chance for defence on the Upper Lakes that she can never enjoy without it. This canal might be considered by the Dominion Government on the same basis as colonization railways which have been freely encouraged all over Canada.

(c) The possibility of the enlargement of the St. Lawrence system is as yet undetermined, as it requires the co-operation of the United States;

(d) The cost and value of the power development thereon is unknown as no international agreement, surveys or estimates have been prepared;

(e) The enlargement of the Welland Canal without a corresponding enlargement of the Welland-St. Lawrence system will at least benefit United States quite as much as Canadian interests, and it is questionable if it will not divert trade from Montreal to New York.

(f) It will give the United States control of Lake Ontario in case of international trouble, and be an important factor contributing to the probable loss of the wealthiest and most populous part of Canada.

The Dominion Government has recently appointed a Commission to report on the proposed Ottawa Ship Canal, which doubtless will add much to the present knowledge of the commercial feasibility of this project, and it is to be hoped of an alternative project of a 14 ft. barge canal.

It is to be hoped that it will also give some similar information regarding the enlargement of the Welland Canal and the proposed extension of the enlargement to Montreal that will guide the Government in deciding on the wisdom of such vast expenditures of public money before the projects are actually undertaken.

It is to be regretted that a similar Commission had not been appointed before the Government committed the country to the expenditure of several hundred millions, on the simultaneous construction of two additional transcontinental railways, and numerous other expensive projects.

The Chemistry of Portland Cement

A research to determine the Chemical Constitution and Best Method of Production of this All-important Building Material

(Concluded from Feb 23)

By G. A Rankin

Three Types of Cement

The similarity of these three types of cement clinkers is not surprising if we consider their chemical compositions. The content of lime, alumina, silica of each type is over 90 per cent., while the composition relative only to these three oxides approaches a constant, the maximum difference being 2.5 per cent. in the case of alumina, since there is 6.5 per cent. in white cement and 9.0 per cent. in gray cement. We should expect, therefore, and it has been found experimentally to be true, that these three types of cement clinker are made up largely of the same constituents; these are, as we have shown, tricalcic silicate, dicalcium silicate, and tricalcic aluminate, all compounds of the three major components of cement.

Having shown that the components of Portland cement are CaO, Al_2O_3, SiO_2 in certain rather definite proportions and that the constituent substances are definite compounds of these oxides, let us consider the percentage of these compounds in the clinker. For example, let us take the average gray cement whose chemical composition has been given in Table I. If the clinker for this cement has been perfectly burned, it will consist of about 36 per cent. $3CaO.SiO_2$. 33 per cent. $2CaO.SiO_2$, 21 per cent. $3CaO.Al_2O_3$, and 10 per cent. of the minor constituents.

In the actual manufacture of Portland cement, however, the clinker is not always perfectly burned, that is, the raw materials are not always ground fine enough or heated to a sufficiently high temperature so that the chemical reactions are completed. The proportions of the constituents in commercial cement will then be somewhat different from those given. With our present knowledge of the nature of the chemical reactions, however, it is possible to state which of the constituents will not be completely formed. It will be remembered that, in the discussion of these chemical reactions, it was shown that $3CaO.SiO_2$ is the last constituent to form completely and this compound is formed by combination of CaO with the compound $2CaO.SiO_2$. It is evident, therefore, that when commercial clinker is not perfectly burned, there is less $3CaO.SiO_2$ and more $2CaO.SiO_2$ and CaO will be present as an individual constituent. In the example given there will be less than 36 per cent $3CaO.SiO_2$, more than 33 per cent. $2CaO.SiO_2$ and there will be a certain percentage of free CaO. The exact percentages will of course depend upon how near to completion the reaction, $CaO+2CaO.SiO_2=3CaO.SiO_2$ has been carried.

Complete Reaction

That the manufacture of good Portland Cement necessitates that this reaction be carried practically to completion is evident if we consider certain facts in regard to the influence of lime on the physical properties of Portland cement. Practical experience has shown that cements containing much free lime are unsound and that concrete made from them will in time disintegrate. This is due to the expansion of free or uncombined lime, when it reacts with water to form calcium hydrate. If, however, the lime in cements is all combined, they are sound and of good strength. The importance of the reaction $CaO+2CaO.SiO_2=3CaO.SiO_2$ is, therefore, apparent, since this reaction must go practically to completion in order that a sound cement may be produced. It has long been recognized that anything which will promote the combination of lime during burning will promote soundness in cement and that the greater the percentage of combined lime the greater the strength of the cement.

The average lime content of cement today is about 62.5 per cent., which is largely combined as $3CaO.SiO_2$,

$2CaO.SiO_2$ and $3CaO.Al_2O_3$. If the percentage of CaO were increased, it would tend to combine with the $2CaO.SiO_2$ to form more $3CaO.SiO_2$ and would so combine if the time of burning were long enough and the temperature sufficiently high. Since practical experience has shown that increased percentage of lime increases both the percentage of $3CaO.SiO_2$ and the strength of cements, it may be inferred that the strength of cements is largely due to the compound $3CaO.SiO_2$. If this is true, it is desirable that Portland cement should contain as high a percentage of this compound as is possible. An average Portland cement contains about 30 to 35 per cent. of this constituent. That Portland cement contains such a small amount of $3CaO.SiO_2$ is due partly to the fact that this constituent is formed with great difficulty and also to the fact that about 40 per cent. is the maximum yield which could be obtained from raw materials having the same CaO, Al_2O_3, SiO_2 composition as are now used.

Before taking up, however, a discussion of the probable value of $3CaO.SiO_2$ as a cementing material and the possibility of increasing its percentage in Portland cement, let us consider what is known as to the cementing value of the constituents of Portland cement, taking up first the changes which take place when Portland cement is mixed with water and hardens.

Chemical Action With Water

When Portland cement is finely pulverized and mixed with water, a hard mass is formed by chemical action between the water and the constituents of the cement. While there is still much to be learned as to the chemistry of the hardening of Portland cement, sufficient data on the hydration of the individual major constituents have been obtained to enable us to account for the gradual hardening and increase in strength and to indicate the relative value of these constituents as cementing materials.

Let us now consider the hydration of the three major constituents $3CaO.Al_2O_3$, $3CaO.SiO_2$, $2CaO.SiO_2$ in the order named. When pure $3CaO.Al_2O_3$ is mixed with water, an amorphous hydrated material is first formed. This material sets and hardens very rapidly. The compound $3CaO.SiO_2$ when mixed with water, also sets and hardens rather rapidly. In the case of this compound, as in the case of $3CaO.Al_2O_3$, the setting and hardening is due to the formation of an amorphous hydrated material on the individual grains which are thus cemented together. The extent of the hydration or the percentage of amorphous material which each grain will yield depends upon the percentage of water used and the time. With a given percentage of water the amount of amorphous material formed from the amount of the compound $3CaO.Al_2O_3$ in a given time is much greater than for the compound $3CaO.SiO_2$, that is, the compound $3CaO.Al_2O_3$ reacts with water much more rapidly than the $3CaO.SiO_2$. The compound $2CaO.SiO_2$ reacts very slowly with water and it is only after a long period of time that sufficient amorphous hydrated material is formed to cement together the grains of this compound and so form a hard mass.

The amorphous hydrated material formed by the action of water on the constituents of cement, does in time, no doubt, crystallize to some extent. From the data available it would appear that the crystals formed are calcium hydrate and some crystalline hydrate derived from $3CaO.Al_2O_3$. Apparently no crystalline hydrate of the calcium silicates is formed.

From this brief description of the action of water on the constituents of Portland cement, it will be seen that the setting and hardening of Portland cement involves the formation of an amorphous hydrated material which subsequently partially crystallizes; that the initial set is probably due to the hydration of $3CaO.Al_2O_3$; that the hardness and cohesive strength at first are due to the cementing action of the amorphous material produced by the hydration of this aluminate and of the $3CaO.SiO_2$; and that the gradual increase in strength is due to further hydration of these two compounds together with the hydration of the $2CaO.SiO_2$.

Of the three compounds which thus take part in the setting and hardening of Portland cement, the $3CaO.SiO_2$ appears the best cementing constituent; that is, this compound is the only one of the three which when mixed with water will set and harden within a reasonable time to form a mass which in hardness and strength is comparable to Portland cement. The compound $2CaO.SiO_2$ requires too long a time to set and harden, in order to be in itself a valuable cementing material. The compound $3CaO.Al_2O_3$, while it sets and hardens rapidly, is rather soluble in water and is not particularly durable or strong.

From this, again, it follows that the compound tricalcium silicate is the essential constituent of Portland cement, consequently the higher its percentage the better the cement. Granting for the time being that this is true, let us consider the nature of an investigation which might lead to the production of a cement containing a much higher percentage of $3CaO.SiO_2$ than is contained in Portland cement as made today.

Effect of Lime

In the discussion of the constitution of Portland cement we have shown that an average Portland cement contains about 30 to 35 per cent. tricalcium silicate, a proportion which closely approaches the maximum yield if the components are in the proportions of an average Portland cement. It has also been shown that an increase in the lime content of an average cement will increase the percentage of $3CaO.SiO_2$ if the conditions of burning are such that the reaction $CaO+2CaO.SiO_2=3CaO.SiO_2$ goes to completion. This, however, necessitates finer grinding of the raw materials, as well as burning for a longer time and at an increased temperature, factors which materially affect the cost of production. Now the data discussed above were obtained by applying the results obtained by an investigation of the equilibrium relations found to exist in the system CaO-Al_2O_3-SiO_2, to the actual manufacture of Portland cement; but this by no means implies that in presence of other components the conditions required for the production of an adequate amount of flux should not be more favorable and economical. In other words, the study of other systems may establish the economic possibility of producing a cement containing a high percentage of tricalcium silicate. For example, if some substance were substituted for the component Al_2O_3, in the system CaO-Al_2O_3-SiO_2, the study of the equilibrium relations found to exist in this new system would enable one to determine whether or not it would be economically possible to produce a cement containing a high percentage of $3CaO.SiO_2$ from raw materials of which the components are CaO, SiO_2, and this third substance. Thus if Fe_2O_3 were substituted for Al_2O_3, we could from the study of the system CaO-Fe_2O_3-SiO_2 ascertain the fineness of the raw material, and the time and temperature of burning, necessary to secure a clinker containing the highest percentage of $3CaO.SiO_2$ which could be economically produced from raw materials of which the major components are CaO, Fe_2O_3, SiO_2. This would require that one determine the nature of all compounds formed in mixtures of these three oxides which, when burned, contain $3CaO.SiO_2$, and that we establish the identity, melting temperature, and rate of formation, of $3CaO.SiO_2$ in such mixtures. Instead of substituting a single substance, it would undoubtedly be more desirable to substitute a number of different substances, since the presence of several produces a lower melting flux and thus makes possible the formation of $3CaO.SiO_2$ at a lower temperature. By proceeding in this way to determine systematically the various mixtures of substances, which, when burned, give high percentages of $3CaO.SiO_2$, it would not seem at all improbable that we may discover some mixture which could be economically manufactured and which would result in the production of a cement far superior to the Portland cement now made.

Essential Constituent

In this discussion we have assumed that tricalcium silicate is the essential constituent of Portland cement. If subsequent investigation should show that other constituents possessed superior cementing qualities, the nature of an investigation to determine the mixture which would economically produce the highest percentage of such a constituent, would be of the same general nature as that described for tricalcium silicate. Indeed, the determination of the constituents (compounds) which possess the best cementing qualities for various purposes may be determined in just this way, since the systematic study of the components found in cements enables one to isolate the separate compounds formed and to determine their cementing qualities pure and in mixtures.

In conclusion, let us recapitulate the main points contained in this paper. The value of Portland cement depends upon the fact that when finely powdered and mixed with water it forms a hard mass; and the strength and permanence of this mass depend upon the constituents of the cement. The major constituents are tricalcium silicate, dicalcium silicate and tricalcium aluminate. Of these constituents, the compound tricalcium silicate is the one which hardens and develops the greatest strength within a reasonable time. This most important constituent, which is the one formed with the greatest difficulty, makes up only about 30 to 35 per cent. of an average normal Portland cement. It may be said, therefore, that the essential process for the manufacture of Portland cement is the formation of this compound, and that any improvement in this process yielding an increased percentage of tricalcium silicate will increase the cementing value of Portland cement. In order to determine the most economical process for producing tricalcium silicate in the highest percentages, it will be necessary to study the rate of formation of this compound in series of mixtures of various substances; this, in turn, necessitates the determination of the equilibrium relations of tricalcium silicate at high temperatures in such mixtures. Such a procedure will lead sooner to the discovery of the optimum composition in various cases and for various purposes than the empirical cut-and-try methods which hitherto have been the only method tried.

Prof. E. Brydon-Jack read a paper entitled "Movable Bridges" on February 3 before the Manitoba Branch of the Canadian Society of Civil Engineers.

Protection of Concrete During Hot Weather

It is not at all uncommon to hear prominent engineers say that concrete placed during periods of extreme hot weather is in general weaker than that placed in winter, says the Contractor, if the materials are heated and the surface protected after placing. If it could be forcibly impressed on the minds of inspectors and contractors that protection of concrete surfaces from the direct rays of the sun during hot days is just as important as protection against cold in winter, this probably would not be true. There seems to be an erroneous idea prevalent among construction men that concrete should harden as rapidly as possible. They believe that concrete dries out in hardening similar to the action of lime mortar and therefore they provide no protection while the concrete is hardening. This state of affairs is no doubt due to the passing of many masons and helpers from their original field into the concrete field. Some of these so-called practical men will not be converted from this erroneous view and a vigorous campaign should be started against such ideas.

The very name "hydraulic" as applied to cements conveys the idea that water is required in the process of hardening. Exposed surfaces of fresh concrete should be protected from the direct hot rays of the sun by boards, building paper, or tarpaulins until final set has taken place; after this it is important that the concrete be kept moist for a period of a week or more after placing. If not kept moist and protected, there is danger of the water which is required for the process of setting and hardening becoming evaporated and the concrete "dried out" before the cement has set. Concrete that has prematurely set or dried out is never as strong as if kept moist while setting, and many times ultimate failure is laid to poor cement or aggregate when in reality the cause was lack of water while hardening.

The statement that the strength of concrete increases with age does not hold good if sufficient water is not supplied throughout the first stages of the hardening process. If the moisture is withdrawn from the concrete the increase in strength is arrested; and even if water is applied later it will do no good toward increasing the strength.

When concrete is unprotected and hardens rapidly, the tendency toward contraction is greatly aggravated and the outer surface is very likely to become "crazed" or covered with "hair cracks" and rendered otherwise unsightly. If concrete dries rapidly the color will be much lighter than if kept damp and allowed to harden slowly.

After an exposed concrete surface has received its final set, it should be covered with burlap (not cement sacks, they are too valuable) or wet sand spread over the surface to a depth of about one inch and kept wet by sprinkling. Where surfaces are not exposed but the concrete section is thin, the forms are likely to be very light, and if exposed to the sun will dry out quickly and absorb moisture from the concrete next to the forms. For this reason it is important to see that such forms are thoroughly soaked daily for a period of a week or more. Impress upon the contractor, inspector and workman that water is an essential element in the proper curing of concrete and better concrete will result.

Aggregates for Concrete Roads

Important advances made in the knowledge of concrete aggregate which compose 80% of material in a concrete road—Life of concrete roads depends on the durability, grading, cleanness and chemical composition of the aggregates

(Concluded from March 1st)

By D. A. Abrams

Experience in the selection of materials for concrete roads has indicated the importance of strength tests, particularly of fine aggregates. For strength tests of fine aggregates a 1:3 mortar mix has become standard, largely for the reason that differences in the mortar-making quality of the aggregate are emphasized by a comparatively lean mix. The standard tension briquet has been generally used for such tests. Recent experiences in the testing of aggregates have suggested that the briquet test of mortars may be of questionable value as a criterion of the concrete-making quality of any material. This has led to inquiry as to whether compression tests of sand mortars or concretes in which the aggregates in question are used may not be a safer guide.

It should always be recognized that mortar strength tests of fine aggregates are purely comparative. The actual values obtained in the test will depend largely on factors which cannot be covered by specification requirements, such as the properties of the cement used and minor differences in manipulation. Comparison of mortar strength with that of standard sand mortars seems to give satisfactory results.

In the "Proposed Specification for Concrete Aggregates," which accompanies this report, no mention is made of the form of specimen to be used. The proposed test for fine aggregate gives a direct comparison with standard sand mortar. The only requirements are that a 1:3 mix shall be used, that the plasticity of the mortar be similar, that the parallel sets of specimens be made by the same operator using the same cement, and that they be made, stored, and tested in the same manner. This leaves the form of specimen optional. It is suggested that compression tests be made on 2 by 4-inch or 3 by 6-inch mortar cylinders until a standard procedure for compression tests is agreed upon.

There is great need for a standard compression test for concrete which will enable comparisons of coarse aggregates to be made. Studies have already been directed toward the selection of a graded gravel or a crushed stone which may be used as a "standard coarse aggregate." Such a material would then bear the same relation to strength tests of concrete made of different coarse aggregates that standard Ottawa sand now bears to tests of mortars from fine aggregate.

Aggregate Materials

Information furnished by the Association of American Portland Cement Manufacturers indicates that the coarse aggregates used in concrete roads built in the United States to date may be classified as follows: crushed rock, all kinds, 55 per cent.; gravel, 40 per cent.; miscellaneous materials, 5 per cent. Natural sands account for nearly all the fine aggregate.

Granites and trap rocks, quartzite, conglomerates, hard limestones, sound, clean sands and gravels, close-grained sandstones and dense blast furnace slag of proper chemical composition are excellent aggregates for concrete roads; soft limestones, inferior sands and gravels, and other questionable materials should not be used in concrete roads.

It has not been considered feasible to present data on the distribution methods of production and cost of concrete aggregates.

Aggregate Specifications

Specifications for aggregates for concrete road building should be based upon definite requirements which are defined by tests of such an exact nature that only high-grade materials will be admitted. The ideal specification would define certain qualities by which all materials could be measured. This would probably imply carrying out a wear test of the finished concrete. Our present knowledge of the effect of variations in the materials used and the methods employed in making and handling concrete do not enable us to do this. The tendency has recently been in the opposite direction; namely, to fix different specification requirements for each class and size of aggregate material.

In the absence of information upon which to base a general specification, certain requirements for grading, cleanness, and mortar strength are found serviceable. The proposed specification for aggregates presented is based on the requirements of fine and coarse aggregates for one-course concrete road construction. A change in the maximum size of the coarse aggregate will be necessary to adapt the specification to the requirements for the top course of a two-course road. In the base of a two-course road, materials of a somewhat lower quality may be used, if it is economical to do so.

Some phases of the specification requirements for aggregate were discussed under "Aggregate Tests." The fine aggregate specification is directed with particular reference to natural sands.* The form of specimen to be used is left optional for the reason that both tension and compression tests are in use. The present trend of practice seems to be in favor of a compression test. The sliding scale of ratios between the strength of concrete sand and standard Ottawa sand mortars is based on the desirability of placing a premium on the results of the older tests.

Proposed Specifications for Aggregates for One-Course Concrete Roads

Aggregates: All aggregates used shall conform to the requirements of these specifications. Before delivery of material at the site of the work the contractor shall submit to the engineer a sample weighing not less than fifty (50) pounds of each of the fine and coarse aggregates proposed for use. The engineer shall determine, by means of tests, whether said samples comply with the requirements of these specifications. The acceptance of samples shall not be con-

* Mr. Mattimore votes "no" on the inclusion of screenings under the specifications for fine aggregates; and "no" on the value of 1 10 for the ratio of the ratio of the strength of fine aggregate mortars to standard Ottawa sand mortar at the age of 7 days.

strued as a guarantee of acceptance of other lots of material from the same source. The engineer may make tests on all lots of aggregate delivered on the work in order to determine whether specification requirements are met.

Fine Aggregate: Fine aggregate shall consist of natural sand or screenings from hard, tough, durable rock or gravel consisting of quartzite grains or other equally hard material graded from coarse to fine with the coarse particles predominating.

Fine aggregate, when dry, shall pass a sieve having four (4) meshes per linear inch; not more than ninety (90) nor less than fifty (50) per cent. shall be finer than a sieve having eight (8) meshes per linear inch. Not more than twenty (20) per cent. shall be finer than a sieve having fifty† (50) meshes per linear inch, and not more than five (5) per cent. shall be finer than a sieve having one hundred (100) meshes per linear inch. The above-mentioned percentages shall be computed on the basis of weight. Fine aggregate shall contain no vegetable or other deleterious materials, and not more than three (3) per cent. of the clay or loam, by weight.

Fine aggregates which give a mortar strength equal to or higher than the minimum value at any of the ages named below, shall be considered as fulfilling the mortar strength requirements of this specification.

Age at Test	Minimum Strength of 1:3 Fine Aggregate Mortar
72 hours	1.25 times (A)
7 days	1.10 times (A)
28 days	1.00 times (A)

(A) equals the strength of 1:3 standard Ottawa sand mortar specimens of same form and size, of similar plasticity, made by the same operator using the same cement.

The tests shall be made on mortars composed of one (1) part Portland cement and three (3) parts, by weight, of fine aggregate or standard Ottawa sand. The test specimens shall be made, stored, and tested in the same manner. All mortar strength tests shall be made under laboratory conditions in accordance with recognized standards. Each value shall be the average from tests of not fewer than three (3) specimens.

Coarse Aggregate: Coarse aggregate shall consist of clean, hard, tough, and durable crushed rock or gravel. Coarse aggregate shall contain no vegetable or other deleterious matter, and shall be free from soft, flat, or elongated particles.

Coarse aggregate shall be graded from two (2) inches down. The coarsest particles shall pass a two (2)-inch round opening. Not more than five (5) per cent., by weight, shall be finer than a sieve having four (4) meshes per linear inch.

Ready-Mixed Aggregates: Run-of-crusher stone, run-of-bank gravel, or other ready-prepared mixes of fine and coarse aggregates, shall not be used.

Field Inspection of Concrete Aggregates

Field inspection of concrete aggregates is understood to include visual inspection and all determinations which can be made by means of the physical senses and such apparatus as may be found ready at hand or conveniently carried about. It is recognized that the value of field inspection depends entirely upon the experience and training of the individual making such inspection. It is usually assumed that field tests are of such a simple character and of such an approximate nature that they can be carried out and properly interpreted by men of little or no experience in the use and testing of such materials.

The field tests which may be applied to advantage depend upon the nature, location, and previous treatment of the material. A careful examination of the surroundings from which a material comes and an inspection of the operation of the plant producing it frequently furnish valuable guides.

Field tests are frequently relied upon to give information as to the probable durability of a material, its cleanness, and grading. A sand which consists largely of soft particles, or is too fine, or contains a large percentage of impurities may properly be rejected on the basis of field inspection.

The grading of aggregates with reference to the amounts passing certain sieves can be determined roughly by means of a set of portable sieves. In the case of coarse aggregates a visual inspection will reveal the presence of large amounts of clay, loam, or soft pebbles in a shipment of gravel, and will indicate whether the material deviates largely from the proper grading.

A fairly exact determination of cleanness of sand may be made in the field by filling a cylindrical glass jar or bottle about half full of sand and adding sufficient water to cover the sand to a depth of 2 or 3 inches. Close the top of the vessel and shake vigorously for a few seconds; then set aside and allow the suspended material to settle on top of the sand. The length of time required for the water to become clear and the depth of the deposit on the surface of the sand give a measure of the foreign material present. If a graduated glass cylinder is used for this purpose a more accurate determination of the silt content of a sand can be obtained. This method sometimes fails in the tests of sands, which, on account of the color or grading, do not show a line of separation between the silt and sand. It should be noted that the results of this test cannot be compared directly with those obtained by the usual laboratory methods made on the basis of the loss of weight. In the field test mentioned above, the silt is determined on the basis of volume; the results are also influenced by the fineness of the silt and effect of the buoyancy of the water. This test will show a silt content varying from 60 to 200 per cent. of that found by the laboratory method in which running water is used and in which the loss is determined on the basis of weight.

Certain engineering organizations have provided their field inspectors with outfits consisting of two or three sieves, a glass graduate, rule, etc., which in the hands of intelligent men may be expected to give fair indications of the literature on the use and testing of concrete aggregates:

While the evidence of field inspection and tests should never be overlooked, it is generally recognized by progressive engineers that such tests are not sufficient for the purpose of discriminating between several lots of available materials, all of which may be of a good grade. Field tests may enable the engineer to determine whether a material complies with certain minimum requirements of a specification, but they give no reliable indication of the relative merits of different materials, and may prove wholly misleading. Field tests such as those described above reveal the presence of impurities, but they give no indication of their effect on the setting and hardening of the cement and on the

† The No. 48 sieve has openings of the same size as the usual No. 50 sieves.

final strength of the concrete. These remarks apply with particular force to natural sands.

A few engineers have carried field tests to the extent of making up blocks of mortar or concrete. By noting whether the concrete hardened satisfactorily, and by breaking with a hammer after a few days, or by loading to failure as a beam, they are assured that no serious mistake is being made. This, however, is a recognition of the value of tests of concrete aggregates, and amounts to conducting makeshift laboratory tests in the field.

Differences in the grading, hardness, silt content, etc., of sands, exert such an important influence on the strength, durability, and watertightness of concrete that the selection of suitable aggregates cannot properly be left to makeshift methods. Most engineers are now agreed as to the importance of properly-made laboratory tests for determining the relative value of aggregates for use in concrete roads.

Mainly Constructional

East and West—From Coast to Coast

The Alabastine Hardmortar, Ltd., have been succeeded by the Toronto Builders' Supply Co. Ltd.

The Toronto Plaster Company, Ltd., has been succeeded by the Toronto Builders' Supply Co., Ltd.

The Montreal Quarry Construction Supply Company, Ltd., Montreal, Que., have been granted a charter.

Plumbers' Exact Supplies, Limited, is the name of a new concern at Fredericton, N. B., with a capital stock of $20,000.

The value of the building permits issued in Welland, Ont., up to the end of February was $4,993, as against $3,270 for the corresponding period of 1915.

Vancouver building permits for the week ending February 26 numbered thirteen, and totalled $14,724 in value. This indicates greater building activity than for many weeks past.

Mr. Thomas I. Jackson, a well-known contractor of Ottawa, has enlisted, and will go to the front with the 156th Battalion, now stationed at Brockville. Two of Mr. Jackson's sons have also joined the colors.

The Callander Foundry and Manufacturing Company, Limited, has been formed with a capital of $40,000 and head office at Guelph, Ont. The provisional directors are J. M. Ferguson, J. P. Walsh, and A. C. Rutherford, all of Toronto.

The New York State Assembly recently passed a bill appropriating $10,000,000 for highway work in upstate counties. The money will come out of the second $50,000,000 highway bond issue, which has been apportioned among all the counties of the State except the five counties in New York City.

The Standard Marble and Tile Company, Limited, has been incorporated with a capital stock of $150,000 and head office in Toronto. The incorporators are F. C. Dunham, G. R. Sproat, F. M. McDowell, C. H. Kemp, and R. Sheppard, all of Toronto.

The members of the Toronto Section of the Ontario Architects' Association have expressed their strong commendation of the action of Mr. W. W. Pearse, city architect of Toronto, in refusing to set aside the building restrictions by granting a permit for the enlargement of the Gem Picture Theatre. The city by-laws of Toronto say that all houses seating over 500 must be of fireproof, first-class construction. The city council apparently overlooked this bylaw and voted by 11 to 5 in favor of allowing alterations to be made to this theatre whereby the seating capacity would be increased from 471 to 771, without making the building of fireproof construction. The matter was quickly adjusted however when Mr. Pearse explained the situation.

The painters and paperhangers of Regina, who have been out on strike for over a week, have returned to work. The strike was holding up two large contracts—the Simpson Building and the Regina College. It is understood that the men have returned to work pending a satisfactory arrangement regarding the scale of wages at a later date.

There were 165 building permits applied for during the month of February in the city of Toronto. These involved an expenditure of $627,329. In the same month of 1915 the number of applications was 149, with a value of $364,821. The number of permits issued during the month was 156, representing an expenditure of $191,459, as against 136 and $199,600 in the same month of 1915.

Until the independent commission appointed to investigate the aqueduct on the Greater Winnipeg Water District line has fully inspected the cracks that have appeared, and reported on the best method of procedure, there will be no more work on the project, according to an announcement made by Mayor Waugh, of Winnipeg. It is hoped that this report will be ready by May 1. The commission was appointed on February 25.

At the annual convention of the Western Ontario Clay Workers, held in London, Ont., last month, D. Wigle, of Kingsville, and R. Wehlan, of Windsor, were appointed a committee to investigate conditions at border points, especially Windsor, where it is claimed Detroit brick manufacturers are shipping in huge quantities of bricks, and after paying duty, selling at a much lower price than Canadians The Government will be asked to increase the tariff.

The Mainland Engineering Company, Limited, Victoria, B. C., has been incorporated to take over the plant and goodwill of the Mainland Iron Works, in liquidation, from the purchaser, Mr. Charles R. Gordon. The consideration for the purpose is 32,000 shares in the new company, fully paid up, and the assumption by the company of $18,000 owing by Mr. Gordon on the purchase price of the plant. The new company does not take over any of the liabilities of the Mainland Iron Works.

With the prospect of an improvement in building conditions, and a consequent demand for cement, the Union Cement Company of Owen Sound, Ont., have a number of their employees busy overhauling the plant with the object of starting operations early next month. The contract for a hundred thousand barrels just closed with the city of Toronto, will supply something definite to work on for the start. The company have a large quantity of gravel on hand from Griffith's Island, and a contract has been let for the coal supply.

The longest made road in the world is just now nearing completion. It is 3,384 miles in length, and extends from New York to San Francisco. It is designed primarily for motor traffic, but other vehicles will not be debarred from using it. Its average width is about 60 feet, and it passes in a direct line through twelve States and more than 200 counties. It has been christened "Lincoln Highway," after President Lincoln. The famous "Exiles Road," which runs across Siberia from Nishni Novgorod to Ke-akh-ta, a distance of about 5,000 miles, is, of course, longer than the above, but it is not, strictly speaking, a "made road," having been beaten originally into a trail by the feet of the poor exiles in the pre-railroad days.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

I wonder what Premier Hearst and his friends think now of J. R. Fallis, and at the same time I would like to know whether Sir Robert Borden has seen the handwriting upon the wall. Fallis is the man who used to represent Peel county, Ontario, in the local legislature. The Davidson Commission showed him up in connection with profits he is said to have made in purchasing horses for the Government. Many a man has disappeared from public life for dealings of this kind, but Fallis did not see it this way; neither did Premier Hearst. Fallis simply resigned and sought vindication by the re-election route. Peel county electors took a different view of it, however, and turned Fallis' former majority of 627 into a Liberal majority of over 300; a turn over of about 1,000 votes. They have given the first public reply to profiteering methods.

Fallis' defeat is a lesson for Fallis, and a pretty clear announcement of the downfall of any others who follow his ideals. If Fallis had made his commission honestly on the horse deals he should have kept it. Handing it over for a patriotic purpose and then seeking re-election was too much for independent Conservatives to stomach. They simply felt that a member of the Government, in his own interest even, should keep his skirts clear, and they went out and voted against Fallis.

When will political leaders in Canada realize that honesty is the best policy and that clean Government would remain in power indefinitely? That is what I have been trying hard to hammer in, but the task grows more and more difficult, and the Government, instead of taking my good intentions at their face value, has been misconstruing them and classing me with its enemies. If Sir Robert Borden would rise above party politics he would realize that behind these criticisms there lies the best friend the Government could have—the independent citizen who would gladly see him measure up to the stature of a clean and a great political leader.

If Sir Robert Borden fails to see the Peel result in the light of a warning closely related to the Shell Committee situation, he ought at least to recognize it as a public assurance that the people will stand behind him if he tries to stamp out the profiteering business. The defeat of Fallis cannot be taken as a Conservative defeat or as a Liberal victory. It is an announcement of the public temper about profiteering and what it means to any party which fails to stamp it out.

Here is the opinion of a strong Conservative paper (The Montreal Star) on the events in Peel County:—

The electors of Peel County, Ont., are worthy of public congratulations and universal gratitude from the entire people of Canada.

* * *

When Colonel J. Wesley Allison gave evidence some time ago before the Davidson Commission he stated that he "was not the agent of any company which sold pistols to the Government" and did not profit "in any way, directly or indirectly," by such sale. Major General Sir Sam Hughes, however, now classes him as his special confidential agent in securing munition supplies in the United States, and in cutting down war combine prices charged there. The latest evidence about this special confidential agent was read before the commission a few days ago. Samuel M. Stone, vice-president of the Colt Patent Fire Arms Company of Hartford, Conn., tells of an order for 5,000 pistols given to the company, after a conference between the chairman of the company's board, Colonel Allison, and General Hughes at Moira, N. Y. He states that the Canadian Government paid $18.50 for each pistol, while the U. S. Government has for years been able to buy them for $14.50, and that dealers could buy them nearly 20 per cent. cheaper. Mr. Stone adds that the company gave Col. Allison a "present," a very small one indeed considering his services, but a "present" for all that, and that he "would not like to consider Colonel Allison one of our regular staff."

At present Colonel Allison is in Florida for his health. When he comes back we are told he will be called upon to give more information. Perhaps we will then get at the facts—learn how much he got for a "present" and just what he considered his duties to be, as Major-General Sir Sam Hughes' special confidential agent for keeping down war combine prices. Perhaps too, we shall be given an inside account of the conference at Moira between Colonel Allison, General Hughes and the chairman of the Solt Company's Board.

* * *

And, by the way, it is decidedly encouraging to note the evidences of independence being shown in our western provinces. In Manitoba and Saskatchewan the honest electors are beginning to make themselves heard. In British Columbia, two ministers in one week is a fine record against the "corrupt combination," as Sir Hibbert Tupper puts it. Sir Hibbert's active participation in this campaign is all the more significant when we recall that the name Tupper has stood for many years in Canada for staunch Conservatism and rugged honesty.

The handwriting on the wall is becoming crowded. Does Sir Robert Borden still persist in closing his eyes to it?

—SEARCHLIGHT.

Personal

Mr. Philip J. Turner, F.R.I.B.A., recently gave an interesting address on "Belgium; Its People and Its Architecture," before the St. James Literary Society, Montreal.

Mr. C. E. Fowler, C. E., the well-known engineer of Seattle, Wash., delivered an address on Bridge Architecture before the Victoria Branch of the Canadian Society of Civil Engineers on February 22. The address was illustrated by a fine series of photographic slides. Mr. Fowler made a plea for the utilization of art and symmetry in design.

Mr. D. H. McDougall has been appointed general manager of the Dominion Steel Corporation, of Montreal. Mr. McDougall is a Nova Scotian. He began his career at the bottom of the ladder in the service of the Dominion Iron and Steel and Dominion Coal Companies, being employed in various capacities in the mining, mechanical, and civil engineering departments. Subsequently he spent two years in the study of mining and steel works engineering in the United States, and was for a time employed in the engineering department of the New York Central Railway. He returned to Nova Scotia to accept the position of superintendent of the extensive iron ore mining operations of the steel company.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Assiniboia, Sask.
The Town Council are considering the construction of a waterworks system this summer. Clerk, J. R. Nolan.

Calgary, Alta.
The estimates for the year include $65,000 for an addition to the reservoir, $51,600 for re-arrangement of the reservoir mains and $54,560 for paving and grading. Engineer, G. W. Craig; Commissioner, F. Garden.

Elma Township, Ont.
Tenders on the construction of the Peet Drain will be received until March 11th by the Reeve, William Scott, Monkton, Ont.

Humboldt, Sask.
The Town Council will shortly call for tenders on the construction of a concrete reservoir. Estimated cost, $4,000. Clerk, W. H. Stiles.

London, Ont.
The City Council are about to lay 5,000 feet of watermains by day labor. Estimated cost, $11,500. General Manager, E. V. Buchanan.

The City Council will shortly take up the proposal to extend the breakwater at West London and to construct sidewalks on it. Engineer, H. A. Brazier.

Block. Some trades will be sub-let. Approximate cost, $40,000.

Welland, Ont.
The general contract for the erection of an addition to the plant of the Union Carbide Company has been awarded to J. C. Diffin. Reinforced concrete construction. Estimated cost, $20,000.

Residences

Chatham Township, Ont.
The erection of a residence is contemplated by J. Makiosi, Wallaceburg, Ont.

Chesley, Ont.
W. G. Murray, Dominion Savings Building, London, is preparing plans for a bungalow to be built for Wellington Krug, Chesley. White brick construction. Estimate cost, $4,500.

Dashwood, Ont.
William Held has had plans prepared for a residence, estimated to cost $3,000. White brick construction.

Easthope Township, Ont.
Charles Cook, Gravel Road, Stratford, is preparing plans for a residence, estimated to cost $3,500. Milton pressed brick construction.

Eastview, Ont.
Charles Aubrey, Main Street, is about to build a residence, estimated to cost $3,500. Frame construction.

Hagersville, Ont.
Charles Robins, R. R. No. 4, Hagersville, contemplates the erection of a residence.

Hamilton, Ont.
Plans have been prepared for a Nurses' Home in connection with the Mount Hamilton Hospital, and tenders will be called very shortly. Architect, W. P. Witton, Hamilton Provincial & Loan Building.

Ingersoll, Ont.
Plans are being prepared for a residence to be built on Thames Street for E. Wright, care of Wright Dry Goods Company. Red brick construction. Estimated cost, $3,500.

Knowlton, Que.
F. S. Mallory, 65 Adelaide Street E., Toronto, is preparing plans for a residence, estimated to cost $10,000. Tenders will be called later.

Levis, Que.
Plans of a residence are now being prepared for R. Roy by L. E. Auger, 39 St. Jean Street, Quebec. Estimated cost, $12,000.

Cherrier Bunville is having plans of a residence prepared by L. E. Auger, 39 St. Jean Street, Quebec. Estimated cost, $4,000.

London, Ont.
W. G. Murray, Dominion Savings Building, is preparing plans for remodelling a residence for W. Parr, 464 York Street. Work will start shortly. Estimated cost, $5,000.

R. H. Smith, 157 Wharncliffe Road, has commenced the erection of a residence, estimated to cost $3,000. White brick veneer construction.

A. Dickenson, 4 Ingleside Street, has commenced the erection of a residence on Duchess Avenue. Estimated cost, $3,000. White brick veneer construction.

Bert Weir, 493 Adelaide Street, is preparing plans for three residences to be built on Reyburn Street at an approximate cost of $6,000. White brick construction.

William Riley, Glebe and King Streets, is preparing plans for two residences, estimated to cost $3,800. White brick construction.

Mandaumin, Ont.
W. Storing, Brown Homestead, Mandaumin, Wyoming, is considering the erection of a residence.

Niagara Falls, Ont.
Work has been started on the erection of a residence on Bridge Street for Albert E. Goring, 4 Pine Street. Brick and shingle construction.

Ottawa, Ont.
John Wilson, care of F. Wilson, 793 Somerset Street, contemplates the erection of two residences on Irving Street and another on Bethany Street. Brick veneer construction, stone foundation, shingle roofing. Estimated total cost, $9,500.

W. J. Spratt, 157 Sunnyside Avenue, contemplates the erection of a residence, to cost about $4,500. Brick veneer construction.

B. A. Grison, 83 Bank Street, is having plans prepared for a bungalow to be built on Fentiman Avenue at an estimated cost of $3,500, and is also considering the erection of a number of residences to cost about $4,000 each. Stucco and brick construction.

Quebec, Que.
L. E. Auger, 39 St. Jean Street, is preparing plans for two residences for J. and Alcide Samson. Estimated cost, $7,000 each.

Raleigh Township, Ont.
George Davidson has had plans of a residence prepared by James L. Wilson & Son, 80½ King Street West, Chatham. Estimated cost, $3,000. Brick veneer construction.

Sorel, Que.
L. S. Robitaille, Phipps Street, contemplates the erection of four flats to replace those destroyed by fire.

St. Jerome, Que.
Charles Jouivet, 377 Rue Notre Dame, Maisonneuve, is building an addition to his residence, estimated to cost $4 000. Frame and plaster construction.

Thedford Mines, Que.
E. Lacerte, Thedford Mines, contemplates the erection of a residence, and is having plans prepared by L. E. Auger, 39 St. Jean Street, Quebec. Estimated cost, $12,000.

Toronto, Ont.
P. H. Finney, 79 Adelaide Street E., is preparing plans for three residences to be built on Kew Beach Avenue, for E. Elliott, 77 Vermont Street. Frame construction.

W. C. Charters, 808 Kingston Road, proposes to build a large number of residences on the Kingston Road, at an approximate cost of $50,000. Plans are being prepared by P. H. Finney, 79 Adelaide Street E. Frame and brick construction.

E. R. Machon, 168 Oakmount Road, has commenced the erection of a pair of residences on Boon Avenue. Brick construction, shingle, felt and gravel roofing. Estimated cost, $4,200.

Mrs. C. Ray, 583 Spadina Avenue, contemplates alterations to her residence for conversion into apartments.

E. J. Croker, 2t Alton Avenue, has commenced the erection of a pair of residences on Orchard Park Boulevard, estimated to cost $3,500. Smaller trades will be sub-let. Brick construction, shingle, felt and gravel roofing.

E. A. Wilkinson, 151 Balsam Avenue, is receiving tenders on the erection of a residence, estimated to cost $4,000. Brick construction, shingle roofing.

Ellis & Ellis, Manning Chambers, will receive tenders until March 15th for the erection of a residence on Radford Avenue for Dr. Gilmour. Estimated cost, $7,500. Brick construction.

Walkerville, Ont.
The erection of a residence on Kildare Road is contemplated by F. E. Allum, Detroit, Mich. Stucco construction.

CONTRACTS AWARDED

Georgetown, P.E.I.
Work will start in the spring on the erection of a residence for Benjamin Stewart. The general contract has been let to P. Bradley, St. Teresa, P.E.I. Frame construction, concrete foundation, shingle roofing. Approximate cost, $3,000.

Hamilton, Ont.
J. W. Gage, 507 Bank of Hamilton Building, has let the contract for masonry required in the erection of two residences on Belmont Avenue to A. Barnes, 53 Cheener Street, and the carpentry and roofing to George Culp, 227 Glendale Avenue. Estimated cost, $3,500.

Bell, 113 Sherman Avenue N.; heating and plumbing, P. A. Moore, 939 King Street E.; electrical work, Culley & Breay, King Street West.

Ottawa, Ont.
D. L. Campbell, 6 Driveway West, is building a residence on Wilton Avenue, estimated to cost $8,500, and has let the contract for electrical work to E. Headly, 645 Echo Drive. Brick veneer construction, stone foundation, shingle roofing.

W. H. Craig, 245 Fourth Avenue, has commenced the erection of a residence on Carlyle Street, and has let the masonry contract to Beattie & Davidson, Renfrew Avenue, and the brick work to Peerless Brick Company, Ottawa South. Estimated cost, $4,500.

The contract for electrical work required in connection with the apartments in course of erection for W. H. Tate, Bank Street, has been let to P. Ackroyd, 416 Bank Street.

Westmount, Que.
Anglin's Limited, 65 Victoria Street, Montreal, have commenced the erection of a residence on Willow Avenue for T. A. Hubley, 4 Windsor Avenue. Tenders

are being received for electrical work. Estimated cost, $6,800. Terra cotta and plastic brick construction.

Power Plants, Electricity and Telephones

Beckwith Township, Ont.
The Township Council are considering the construction of about twenty miles of telephone lines during the year. Clerk, J. W. Robertson, Carleton Place.

Blenheim, Ont.
The Blenheim & South Kent Telephone Company propose to make extensions to their system. Particulars from C. B. Langford, Blenheim.

Calgary, Alta.
The City Commissioners will receive tenders until 4 p.m., March 15th, for the supply of underground cable. Specifications at office of the City Electrical Engineer.

Castleton, Ont.
The Cramahes Municipal Telephone Company propose to construct their system this year. Secretary, Herman Reynolds, Morganston.

Dashwood, Ont.
Plans are to be prepared at once for the construction of a transmission line between Dashwood and Exeter, with branches to Zurich and Crediton. Owner, H. Eilber, Dashwood.

London, Ont.
The City Council will shortly consider the installation of an ornamental lighting system on the breakwater at West London. Clerk, S. Baker.

Mersea Township, Ont.
The Township Council propose to construct a Municipal Telephone System throughout the Township. Clerk, A. Hairsine, Leamington.

Niagara Falls, Ont
The Hydro Electric Commission propose to let a contract for the supply of lamps and transformers during the year. Superintendent, George Foster.

Toronto, Ont.
Kerry & Chace, Limited, 550 Confederation Life Building, desire to receive prices and other information with regard to the following:—one generator, three transformers, two belted induction or synchronous motors, two air compressors, and one Lydner sharpener. Immediate delivery at Cordova Mines, Ont., is required.

Yamachiche, Que.
The Brunelle Furnace & Boiler Company, Limited, propose to install electric motors and to equip their machinery for electrical operation. Manager, A. Heroux.

Fires

Bout de L'Isle, Que.
The residence owned by Oscar Ribet has been destroyed by fire. Loss, about $8,000. Owner will rebuild.

Bridgeburg, Ont.
Fire has destroyed the residence of W. M. Hogg. Loss, $4,000.

Calgary, Alta.
Fire has destroyed the Central Methodist Church. Loss, $50,000, partially covered by insurance.

Chatham, Ont.
Fire has entirely destroyed the residence of Abram Turner and the residence and barn owned by John Turner.

Clarkson, Ont.
A large barn, belonging to W. G. Gooderham, 42 Elm Avenue, Toronto, has been destroyed by fire. Loss, $30,000, covered by insurance.

Dover Township, Ont.
The Presbyterian Church has been destroyed by fire. Loss, about $8,000. Pastor, Rev. Norman Lindsay, Concession 11, Dover Township, Chatham.

Lake Rosseau, Muskoka, Ont.
Fire has destroyed the Maplehurst Hotel, owned by Mrs. J. B. Brown.

Moncton, N.B.
A residence owned by Dosite LeBlanc, Emmerson Street, has been entirely destroyed by fire.

Montreal, Que.
A business block on St. Catherine St. West has been destroyed by fire. Owner, Fairman Estate, care of F. W. Fairman, 232 St. James Street. Loss, $20,000.

The residence at 313 Beaudry Street, owned by Edmond Porcheron, 636 St. Denis Street, has been destroyed by fire. Loss, about $5,000.

Fire has damaged the premises of the Canadian Metal Manufacturing Company, Limited, St. James and Richmond Streets, to the extent of $15,000.

Fire has destroyed the Bonaventure Station of the Grand Trunk Railway Company. Loss, $300,000.

Orillia, Ont.
J. A. Orton's planing mills have been destroyed by fire. Loss, $7,500, partially insured.

Fire has destroyed the Grand Trunk Railway Station.

Ottawa, Ont.
Fire has damaged the foundry of the Ottawa Steel & Iron Works, 137 Broad Street, to the extent of about $3,000. Owners will rebuild.

Port Hope, Ont.
Fire has destroyed five residences owned by W. R. Chisholm, Church St. Loss, $15,000, partially covered by insurance.

Sarnia Township, Ont.
The residence of Adam Storing, Concession 2, has been destroyed by fire. Loss, $3,000. Owner is considering rebuilding.

St. Catharines, Ont.
Two stores, owned by Marshall's, Limited, have been destroyed by fire. Loss, $18,000, covered by insurance.

Thorold, Ont.
The residence owned by Mrs. C. Baxter, Beidal Avenue, has been destroyed by fire. Loss, $5,000, partly insured.

Toronto, Ont.
Fire has badly damaged the premises of the Toronto Wood Turning Company and the Builders' Moulding Company, 95 Richmond Street West.

Welland, Ont.
The planing mills belonging to S. L. Lambert has been destroyed by fire. Loss, $25,000, partly insured.

Winnipeg, Man.
Fire has destroyed a factory building owned by J. A. Mullaberry, 76 Smith St. Loss, about $9,000.

Miscellaneous

Assiniboia, Man.
The Municipal Clerk, Frank Ness, Kirkfield Park P. O., will receive tenders until noon, March 15th, for all lumber required during the year.

Calgary, Alta.
The sum of $13,000, for the erection of two comfort stations, has been included in the estimates for the year. City Clerk, J. M. Miller.

London, Ont.
The Board of Control will receive tenders until 4 p.m., March 13th, for supplies required during the year, including cement, tile, lumber, gravel and iron castings. Specifications at office of the Engineer, H. A. Brazier.

Toronto, Ont.
S. A. Hager & Son, 703 C. P. R. Building, are receiving tenders on the supply of 3,000,000 of birch, 1-inch, 1½-inch and 2-inch.

Triple Island, B.C.
The Department of Marine & Fisheries, Ottawa, propose to build a lighthouse and fog alarm. Deputy Minister, A. Johnston, Ottawa.

CONTRACTS AWARDED

London, Ont.
The London Concrete Machinery Company, Limited, have been awarded a contract for the supply of two batch mixers for use at the new plant of the Imperial Oil Company at Point Aux Trembles, Que.

Commission Appointed to Advise on Panama Canal Slides

In compliance with a request from President Wilson, who is desirous that General Goethals have the benefit of the best assistance possible in solving the problem he has in hand, the National Academy of Science has designated a commission to investigate the subject of slides on the Panama Canal and to make a report to the President concerning them. It is expected that the commission will sail for the Canal Zone to-day.

Those appointed on the commission are: Charles R. Van Hise, president of the University of Wisconsin; Brig.-Gen. Henry L. Abbot, hydraulic engineer, of Cambridge, Mass.; John C. Branner, president of Leland Stanford, Jr., University; Whitman Cross, of the U. S. Geological Survey; John F. Hayford, director of the college of engineering, Northwestern University; Harry F. Reid, professor of geology at Johns Hopkins University; Dr. Charles D. Walcott, president of the Smithsonian Institute; Rolla C. Carpenter, professor of experimental engineering, Cornell University; Arthur P. Davis, chief engineer U. S. Reclamation Service, and John R. Freeman, consulting hydraulic engineer, of Providence, R. I.

Tenders and For Sale Department

Tenders Wanted

Tenders are invited for the erection of a Brick Veneer School House on the Town Line of Moore and Sombra, Lambton County. Plans and specifications can be seen at the house of F. K. Johnson, Secretary-treasurer, or C. O'Connors, Chairman of the School Board, Bickford. Tenders to be opened March 20th, 1916. 9-11

The lowest or any tender not necessarily accepted.

Notice is hereby given that the time for the reception of tenders for Lock Gates and their equipment, at East River Lock, N.S., near New Glasgow, is extended to **Monday, March 13, 1916.**

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
9-9 Ottawa, Feb. 24, 1916.—93423.

CITY OF BRANTFORD

St. Augustin, Que.

The School Board propose to erect a school at an approximate cost of $15,000, and are having plans prepared by L. E. Auger, 39 St. Jean Street, Quebec.

St. Hilaire de Dorset, Que.

L. E. Auger, 39 St. Jean Street, Quebec, is preparing plans for a church to be erected for the Roman Catholic congregation. Estimated cost, $14,000.

Wheeled Spout Aids Concreting of Levee Slopes

Concrete protection for the river base of a 1,600-ft. levee has recently been poured economically in alternate up-and-down strips by a light, sectional wheeled chute which delivered concrete from a mixer moved along the top of the embankment.

The dike will protect a thickly-settled section of Binghampton, N. Y., from floods on the Chenango River, which four times in recent years has inundated this part of the city. The entire levee is 2,600 ft. long, the earth portion being built across the smaller, westerly channel of the river to Comming's Island. The east channel and part of the island was dredged out with a dragline and removed with a steam shovel and cars to provide material for the embankment. Most of the bank required a 20-ft. fill, the maximum being 35 ft. This brings the top of the levee to 26 ft. above low water and 6 ft. above the highest recorded flood. The remaining section of the dike consists of a steel-sheet-pile section 475 ft. long and a 500-ft. concrete wall.

The 6-in. reinforced concrete slabs of the river face of the embankment were cast in alternate 10-ft. strips, using forms similar to sidewalk forms. They are carried down 4 ft. below low water mark. Although it was expected that dry mixture would have to be used, it was found possible to hold a thoroughly wet mix on the 2-to-1 slope. The sectional chute, designed and furnished by the Foote Manufacturing Company, which supplied the mixer, was supported on wheels which rolled on scantlings laid at intervals across the top of the forms. The slabs for this section of the work were reinforced 2 in. from the bottom with No. 41-gage woven wire mesh to minimize damage from ice jams. The 1,800 cu. yd. of 1:2:4 concrete laid on the levee slope cost $7.90 per cubic yard. according to John A. Giles, city engineer of Binghampton, who had charge of the project. Arthur L. LaRoch, engineer in charge, supervised the conversation of both sections, while H. W. Fitzgerald was contractor for the embankment section described.

The War's Effect on the Trade Policy of the British Empire

ONE of the most revolutionary results of the war, so far as the British Empire is concerned, will be the utter uprooting of the old ideals of free trade, which have been so great a factor in the political and industrial life of Great Britain. Already the chief exponents of free trade in Great Britain have thrown their former beliefs to the winds and come out definitely in favor of radical changes of fiscal policy, so as to enable the Empire, after the war, to maintain the objects for which it has been fighting and to make it impossible for Germany ever again to obtain that international industrial and commercial preponderance that has enabled her to plunge the world into war.

There is now no room for doubt that Great Britain will never again return to the position she occupied before the war as an isolated free trade nation. Her eyes have been opened to the danger of free trade so long as there are, among others, nations like Germany that will take advantage of it to increase their strength and preparedness for war. The rulers of England to-day are working out the details of this problem and getting ready for the changed conditions which will follow the war. Even now, these changes are to some extent in effect. By the time the war is over England will have much of the necessary machinery in operation, a good deal of the legislation worked out, and the public mind well prepared for the new fiscal policy.

In many ways these changes will work out to the advantage of Canada and the other overseas parts of the Empire. For Canadians the duty is to consider what this change will mean to us, and to see to how great an extent we can co-operate so as to produce, under the new conditions, the greatest advantage both to ourselves and to the Empire. The outstanding business features of the period following the war will be reconstruction and readjustment: reconstruction of the countries which have been devastated, and readjustment of the business relationships and industrial activities which have been shattered by the war. A great deal of consideration has been given to the reconstruction problem. Readjustment of the business and industrial situation, however, has not been considered by the press in general to anything like the extent that it warrants.

* * *

In connection with Great Britain and Canada, and to a large extent also in connection with the allied countries and Canada, the readjustment of business relationships will be of great and vital importance. No single country in the whole world will be in the same advantageous position as Canada. When the war is over, having borne her share of the struggle she will be favored by the allied countries whenever there is a possibility of conducting trade with her. In the markets of Great Britain and France this will be a great advantage to Canadian manufacturers. It will give them the whip hand in all transactions in which Canadian goods can stand any chance at all.

Even when one looks at this question in a broad and general way he cannot fail to be convinced that of all the countries in the world, the one which will develop most rapidly and most substantially after the war will be Canada. Our agricultural and manufacturing products are nearly all of a class that will be in demand in Great Britain, France, Belgium and other European countries. Our manufacturing and producing capacity will be strained to the utmost, and those who have foreseen the situation and placed their affairs in such shape as to take part in Canada's great expansion will reap a greater harvest of business prosperity than they ever dreamed of in the days before the war.

* * *

To put the matter in as brief and simple a form as possible, Canada will, more than ever before, be the Land of Promise and the Land of Fulfilment. Her plants will be running night and day, her merchants will be busy from morn till night. Her farmers will be able to sell at good prices everything that they produce, and this prosperity will attract to the shores of Canada a great tide of immigration. From all parts of the world people will set out for Canada to share in its expansion. The immigration from the United States to Canada which started on an extensive scale only a comparatively few years ago will be renewed and greatly increased. Moreover, from the United States we will then draw not only farmers in large numbers, but a far greater number of merchants and manufacturers than we formerly drew. Manufacturers in the United States will be quick to realize that, if they want to share in the trade of Great Britain and the allied countries to the fullest extent, they must establish plants in Canada so as to be entitled to the preferential treatment which Canada will then obtain.

These are no idle dreams dictated by desire and unfounded on fact. Anyone who reads what is appearing daily in the press of Great Britain regarding the fiscal problem, knows that these views are warranted by the trend of public opinion in Great Britain. Free trade has been killed. The Manchester Chamber of Commerce, the historic hot-bed of free trade, has voted against it by 998 to 527. The greatest exponents of free trade in Great Britain have thrown it over. From now on, every man who thinks about the fiscal problem in the Old Country will think of it in terms of tariff protection. The working out of protection will involve many differences of opinion, but the great change has come about. The war has made protection the only logical policy for Great Britain. After the war, and to a considerable extent during the war, protective tariffs will come into effect and they will unquestionably include preferential treatment for the Overseas Dominions and reciprocity between the Allied Nations.

Cement Bricks

The following inquiries have been received from one of our readers:—

1. Do you think cement bricks and block are to stay?

2. Have they any advantage over the common clay brick?

3. Is a cement brick the better by being made on a machine of heavy pressure?

4. What is the advantage of a frogged brick? Do they lay better than plain pressed brick?

It is always dangerous to prophesy, but Mr. W. W. Pearse, C. E., city architect of the city of Toronto, has been good enough to pass an opinion on these questions, which we print herewith. We also invite further discussion in the hope that further light may be thrown on these interesting questions. Mr. Pearse is of the opinion that cement blocks are here to stay, because they appear to have several advantages over solid brick. Being hollow, they are warmer and drier, though the joints when filled in solid act as fair conductors and offset to some extent the effect of the air spaces. It is very generally accepted that a hollow cement brick wall is warmer in winter and cooler in summer than solid brick. Cement block has the disadvantage, however, of not having as good a bond as solid bricks because it has not the same amount of bearing surface. Therefore much depends on the type of building. If a heavy load is to be carried solid blocks should be used. Hollow cement blocks should be laid in cement mortar on account of the small bearing surface.

Cement brick or block should be better if made under pressure. They will be denser, with the resultant greater resistance to crushing, and should absorb less moisture.

Frog brick properly laid give a better key to the wall than plain brick. The trouble is, however, that unless he is watched the bricklayer will lay the brick frog side down, to save mortar. For this reason it is generally accepted that a wall of plain brick is practically as good as an ordinary wall laid with frog bricks. It is the general practice in the United States to use bricks without frogs.

When Are Concrete Roads Most Profitable?

By H. S. Van Scoyoc, A.M.S.C.E.*

Concrete roads are most profitable when they give better value per dollar of expenditure than any other type of satisfactory surfacing material. While improved roads create values that cannot be measured in dollars and cents, a commercial standard is the one most readily set up.

Constant Costs

With any type of improved highway there are certain expenditures which should remain practically constant regardless of the surfacing used. In all cases the cost of right of way and grading should be a permanent investment; if bridges and culverts are constructed with proper regard for future requirements and of suitable materials they should be practically a permanent investment. Drainage work and foundation courses usually require expenditures other than that of the first cost. Surfaces can never be considered as permanent; while there has been a tendency to neglect some of the preliminary work, where concrete is used it is not to be commended. In the opinion of the speaker the initial cost of concrete highways justifies more careful grading and drainage work than where a less permanent type of construction is used. For the purposes of this discussion, however, it will be considered that all types of permanent surfacing should have the same amount of money expended on the preparatory work.

Concrete roads are made up of cement, sand, stone and labor. The first cost of the concrete will vary as any or all of these items vary. The labor cost for mixing and placing will show the least variation possible. The materials will increase in cost chiefly as the distance from their source to the point of construction increases. For example, the cost in Wayne County, Michigan, where the same materials and same methods are used throughout the county, has varied from $1.04 to $1.70 per square yard, depending upon the length of haul.

Concrete Cheaper than Macadam

There are exceptional cases where concrete roads have been built for lower first cost than waterbound macadam. This happens where no suitable local stone is available for macadam, but local sand and gravel are suitable for concrete. It would also usually presuppose a thickness of macadam greater than that of the concrete. The first cost of cement concrete will usually be less than that for bituminous concrete, brick or other types of permanent paving. It may or may not be less than that for bituminous macadam. In any case, however, the initial cost is a small part of the whole story and should be considered as such. The total road cost can be considered as comprising: first, interest on the first cost; second, depreciation, and third, maintenance, which should include overhead charges for administration and use of machinery as well as the repair charges for materials and labor. In special cases other considerations than the yearly cost on the basis just mentioned may be deciding factors in the selection of the material, as the value of a comparatively noiseless pavement in the vicinity of hospitals or schools. In cities and towns ease in cleaning

*Chief Engineer Toronto Hamilton Highway, before Ontario Good Roads Association.

is important. In any case ease of traction is desirable as affecting not only the actual cost of transportation, but also the expenditure for repairs to vehicles.

Cost Depends on Locality

Any particular locality presents a problem that will give a definite figure if solved along the lines mentioned. As a general proposition, however, certain figures will have to be assumed. A single track road will be considered as nine feet in width and a double track one eighteen feet. Interest will be taken at five per cent., which is possibly low just at the present time, but ought to be sufficient in ordinary cases. In estimating depreciation the concrete will be considered to be satisfactory for use as a sub-base at the end of twenty years. Cases considered will be where local municipalities may be responsible for the entire cost of construction and of the maintenance as well as the other cases that may arise under the new Highways Act. As previously mentioned, the first cost of concrete highways will show a considerable variation, depending upon local conditions. For present purposes a figure of $1.35 per square yard will be used. It should be reasonably safe for most localities where reinforcing and steel protection plates are not used.

Depreciation and Maintenance

A word of explanation as to depreciation and maintenance. Concrete roads are a comparatively new type. Their life is not definitely known. I have seen one street laid twenty-three years ago on which the maintenance cost per year has been considerably less than $50 per mile per year, and there is no present intention of using it as a sub-base for any other type. Some of the Wayne County roads under very heavy traffic are nearly ten years old and are still in good condition. It seems to me that under average traffic conditions limiting the use of concrete to sub-base purposes after twenty years is conservative.

Cost Figures

As to maintenance cost, few figures are obtainable for twenty-year periods, but the report of the Committee on Methods and Costs of Maintenance presented at the Second National Conference on Concrete Road Building states that from present returns one-half cent per square yard seems a conservative estimate.

Roadway Nine Feet in Width

Township Road:

First cost is, 5,280 × $1.35 ... ... $7,128.00

Interest at 5 per cent. $356.40

$$\text{Depreciation } \frac{5{,}280 \times (\$1.35 - 0.75)}{20} = 158.40$$

Maintenance ... ... = 35.00

Total $549.80

Suburban Roads:

		First Cost	Depreciation		Maintenance	Total
Province	40%	$142.56	$63.36	20%	$7.00	$212.92
City	30%	106.92	47.52	40%	14.00	168.44
County	30%	106.92	47.52	40%	14.00	168.44
						$549.80

Main Roads:

		First Cost	Depreciation		Maintenance	Total
Province	40%	142.56	63.36	40%	14.00	219.92
Municipalities	60%	213.84	95.04	60%	21.00	329.88
						$549.80

Road Eighteen Feet in Width

Township Roads.

First cost, 10,560 × $1.35 ... $14,256.00

Interest at 5% $712.80

$$\text{Depreciation } \frac{10{,}560 \times (\$1.35 - 0.75)}{20} = 316.80$$

Maintenance 50.00

Total $1,079.60

Suburban Roads:

Say total cost is $20,000 per mile. Province is limited to $4,000 per mile, or 20 per cent. of construction cost

		First Cost	Depre'n.	Maint'ce	Total
Province	20%	$142.56	$63.36	$10.00	$215.92
City	30%	213.84	95.04	15.00	323.88
County	30%	213.84	95.04	15.00	323.88
Local Imp.	20%	142.56	63.36	10.00	215.92
					$1,079.60

Main Roads:

Province limited to $4,000 per mile.

		First Cost	Depre'n.	Maint'ce	Total
Province	20%	142.56	63.36	10.00	215.92
Municipalities	80%	570.24	253.44	40.00	863.68

These figures may look formidable, but I believe they are representative. Col. Edwin A. Stevens, Commissioner of Public Roads, State of New Jersey, in a recent article stated that with an average daily traffic of 400 vehicles, mixed motor and horse drawn, maintenance of macadam roads with bituminous dressing can be taken at $1,300 a mile, made up of interest $500 (rate 4 per cent.), depreciation $200 and repair charges $600.

Maintenance Cost of Macadam

The 1915 report of the Massachusetts Commission states that especially near the larger cities the maintenance cost of macadam with a bituminous dressing would easily be $1,000 or more per mile annually, this figure not including interest on first cost. In their 1914 report is the statement that the average cost of maintaining over four thousand miles of main county roads in England was $1,100 a mile a year and the average cost of maintaining nearly two thousand two hundred miles of road in and around the city of London was $1,680 a mile a year. The costs given include resurfacing or reconstruction (considered as depreciation in our previous discussion) as well as ordinary repair and maintenance. These figures do not include interest on first cost, however.

The various items mentioned should be carefully considered and properly balanced in deciding upon the particular type of surfacing for any one locality.

Traffic Census

In conclusion, just a word of caution as to depending upon a traffic census of an unimproved highway as a safe criterion of what an improved highway in the same locality will be called upon to carry. In 1908 a seven-mile road which connected Woodward Avenue and Jefferson Avenue, two trunk roads leading out of Detroit in the Wayne County system, was carrying a total of forty vehicles per day. A traffic census last year showed an average daily traffic of almost two thousand vehicles, with a traffic on Saturdays and Sundays of from four thousand to six thousand vehicles.

Tests on Canadian Commercial Brick

Obtaining reliable data on Canadian Building Materials to facilitate estimating and eliminate failures

By W. W. Pearse, C.E.

[Some interesting tests were recently carried out under the supervision of Mr. W. W. Pearse, C. E., city architect of Toronto, on the compressive tensile strength and absorptive qualities of various kinds of building brick. The results of these tests are contained in the following paper read by Mr. Pearse before the annual convention of the Canadian National Clay Products Association. It is understood these tests were made with a view to obtaining information on which a suitable building by-law for the city can be based.—Editor.]

Three bricks were taken in each case, one of which was planed down to an even surface and then placed in a machine and crushed. If there was any chance of it being uneven, it was embedded in plaster Paris. Then, when it came to the bending test, the bricks were taken and supported on supports 7 ins. apart and a central load applied. Following this there was an absorption test made. The samples were put into a furnace, dried, weighed, put into water, taken out and weighed again. (I may say here that the man making the test was not aware whose brick he was testing).

The committee of the American Society for Testing Materials classify the bricks under the following headings:

Class A.—Vitrified Brick—Compression not less than 5,000 lbs. per sq. inch; absorption not more than 5 per cent.

Class B.—Hard Burned—Compression 3,500 to 5,000 lbs. per sq. inch; absorption not more than 12 per cent.

Class C.—Common Brick—Compression 2,000 to 3,500 lbs. per sq. inch; absorption not more than 18 per cent.

Class D.—Common Brick, seconds—Compression not less than 1,500 lbs. per sq. inch; absorption no limit; not to be used in exposed work.

Class C and Class D are more the type of brick which I had tested. It was not necessary to test the ordinary hard brick, for I knew it was safe. We wanted the mercantile brick. This comes under the heading "Class C, common brick." For results, see Table I. In this table the number of brick tested is given first, then the percentage of absorption, the fibre stress and the crushing strength per square inch.

Now, taking the two different tests, we have the crushing stress and the bending stress. If you have what is called lime mortar, which is 1 to 3 mixture, it is very little use paying any attention to the bending stress. The wall would more or less act the same as a beam and have a tendency to open up at the bottom. Lime mortar is of no value in tension, therefore it would be no use considering the tension in the brick. In using lime mortar, you need not take into consideration the tensile strength of your brick, because lime mortar would give way in tension before the bricks could be pulled apart. The stress on the bricks would therefore come down to an angle of about 60 degrees. If, therefore, you are using lime mortar you can exclude the idea of fibre stress and get down to crushing. If you are using cement mortar of 1 to 3 mixture it will work very well. If you had a wall of this nature you could treat it as a beam and make it of much less thickness and depth, because cement mortar, if of good quality, would have an equal strength, approximately, of the ordinary brick in tension and adhesive value, and this would make the brickwork a more or less homogeneous mass.

Referring again to the American tests, they found that a brick wall well laid in lime mortar only sustained 13 per cent. of the crushing value of the brick. For cement mortar you could allow 25 per cent. It is therefore a question of cost. I found, on consulting with different contractors, that the matter of cost was one of importance. On 1,000 bricks laid, $1.70 was the cost of the extra sand, cement and labor; that is, 22½ per cent. extra cost on 1,000 of bricks at the present market value. But you get an extra strength of 92½ per cent. If you could act as pioneers to get the best value out of your products it would be good to have you advocate using as much cement mortar as possible. We had a bad accident recently at the University of Toronto, and it was the opinion of some of the experts that if cement mortar had been used in place of lime mortar it might not have happened. However, this was not proven. It seems to me, however, that for very little extra cost (you can add 10 to 15 per cent. of lime to make the cement mortar

Tests on Bricks.—Table No. I.

Number of bricks Tested	Average percentage of absorption	Average fibre stress lbs. per sq. in. Bending	Minimum crushing strength lbs. per sq. in.	Maximum crushing strength lbs. per sq. in.	Average crushing strength lbs. per sq. in.	Nature of Material
6*	8.1	1026	3555	6215	4453	Hudson Lorraine Shale.
13*	15.8	872	3420	6150	5160	Medina Shales.
7*	12.0	915	3080	6170	4141	Interglacial Clays (Good).
3†	20.6	649	2700	3540	2983	Redeposited Glacial Clays (Good).
17†	17.0	643	2070	4080	2818	Iroquois Clay.
6	10.9	388	1645	4640	2993	Sand Lime, Hydrated.
2	11.3	404	2275	3000	2638	Sand Lime, Quick Lime.
16		481			3920	Western Brick Co. Underburned.‡
	18.0	576			2584	Class "C" Common.§
	No limit	403			1739	Class "D" Common.§

* Hard brick; † Ordinary brick; § University of Minnesota; ‡ University of Illinois, Bulletin No. 27.

work easily) you would get that much additional strength.

Referring to the Western Brick Company's Unburned, Table I., we find that there were 16 tests made, which gave 3,920 lbs. per square inch for the crushing strength. You will notice that Canadian brick compares quite favorably with this. By comparing the crushing and tensile strength with the absorption percentage, it was found that there was no relation between them.

The important thing to this department is,—how much will a brick carry in a wall? There is a difference whether you use lime mortar or cement mortar. We have had no tests made of our large walls, so I had to fall back on the United States. One was by the University of Illinois. The authorities all agreed so very closely on 25 per cent. for cement mortar and 13 per cent. for lime mortar that I adopted this standard.

If, therefore, we want to know what each brick will carry in the wall all we have to do is to multiply the crushing stress per square inch by 144; this will give crushing load in pounds per square foot. Then if cement mortar is used, take 25 per cent. of this value and it will give the approximate crushing load per square foot in a wall that is about nine feet high. Then this result must be divided by whatever factor of safety you may desire to use. I think for a concentric load a factor of safety of five would be a fair figure.

Now, if lime mortar is to be used, it would be safe to take just half of the results given for cement, as we found that for brick laid in lime mortar that you could only use about 13 per cent. of the crushing value of the brick, or approximately half of what you can use when cement mortar is used.

I want you to understand that when we select these bearing qualities, I would like to not only submit the question to your organization, but also to the Canadian engineering societies, so that we can get the very best thoughts on the subject.

Erosion or Weathering

Erosion, so prevalent in many of our public and residential buildings, calls for some explanation of the cause. Almost invariably the material in question is a red sand face brick. The clay from which the bricks are made is either a surface clay or an interglacial deposit common to the neighborhood of Toronto. Like the stratified glacial buff burning clays, they contain a high percentage of combined lime carbonate; in some deposits over seventeen per cent. is present. The buff burning clay is easily vitrified under oxidizing conditions, and does not yield to the decomposing influence of the converted carbonate. The interglacial and surface red burning clays are not vitrifiable under oxidizing conditions, hence the erosion which is so prevalent. To render the lime content impotent in these clays, reducing conditions must be established in the kiln, and continued, until an incipient metallic fusion (often mistaken for vitrification) takes place, but as the fire range is so short greater care must be exercised in the burning of the ware. It would be well to note here that buff burning shale bricks are showing signs of distress through erosion in different buildings in the city owing to what might be termed underburned ware. Although the shales are highly vitrescible it is necessary that a temperature be maintained high enough to vitrify the ware. Incipient decomposition betrays itself in loss of color. Red or dark red bricks gradually change color until they assume the appearance of underburned ware which they really are. At this stage the sand face is lost and they absorb moisture from the air greedily and if not coated with a filler, as paint, quickly waste away. Needless to say that moisture absorbed from the atmosphere quickened the lime content into action which reduced the brick back to its original state, minus the carbonate.

Summary

1. Face brick, being of extra quality, were excluded in deducing the averages, Table I.
2. All the samples secured of brick made from Hudson Lorraine shale by the dry press process are face brick.
3. The weakness of the dry press shale bricks in centre load test in comparison with the wire cut shale bricks is noticeable.
4. The superiority of the shale hollow brick over the glacial clay hollow brick is sufficient to make a second classification advisable.
5. The great variation of the strengths of the bricks made from the glacial stratified clay by three different processes is so noticeable as to require a separate class for each, although but one sample of each was tested.
6. The Iroquois clay when burned in stove kilns gives an inferior grade of brick, the stiff mud bricks being apparently stronger than the soft mud bricks.
7. The interglacial stratified clay when burned in any form of down-draft kiln, gives good bricks by either the stiff or the soft mud process.
8. The sand lime bricks come from plants in which the materials used vary widely in quality. The average is therefore scarcely a reliable criterion for this class of brick.
9. The cement brick that was tested was not very old. A new test will be made.
10. Test No. 73 A, made upon a brick similar to that used in test No. 73 after being allowed to age for a longer time, shows that cement bricks tend to become stronger with age.

Setting the Pace in Contracting

An exceptionally expeditious piece of brick and concrete construction is just being completed by Anglin's, Limited, Montreal. The Williams Manufacturing Company, Limited, Montreal, recently decided to erect an addition to their factory on Bourget Street. Plans were drawn by Mr. J. Cecil McDougall, A.R.I.B.A., and it was desired to erect the building in the shortest possible time. The floor area of the addition is 6,600 square feet, and the building has a frontage of 71 feet. The original plans provided for a structural steel frame, with the steel fireproofed, and mill construction floors. After consideration, and in order to save time, it was decided to change the design to a brick and concrete structure, that is, a reinforced flat slab construction. In this way the firm were able to occupy the two lower floors by the time that would have been taken to manufacture the steel had the original plans been adhered to.

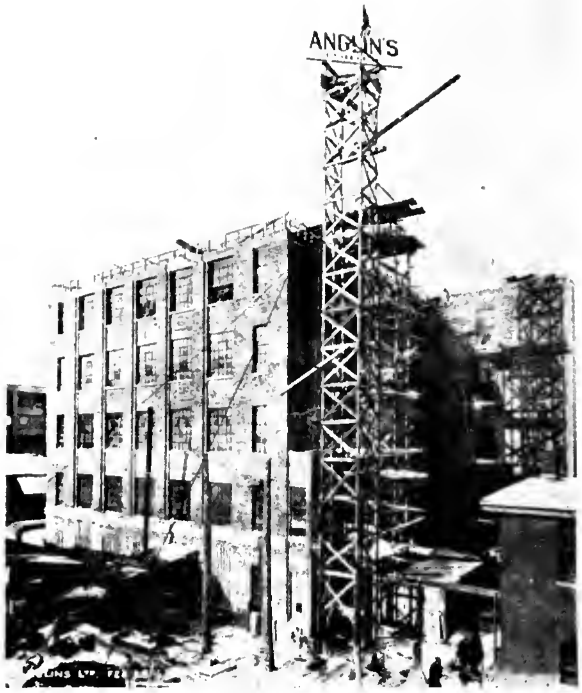
The contract was signed on January 4, one of the conditions being that the ground and first floors were to be ready for occupation on February 15, and the entire five storeys to be completed on March 15th. Operations were commenced on January 5, and the two first floors were ready three days ahead of the scheduled date, when the company commenced installing their machinery. Concrete was poured for the first floor on January 20 and 21; second floor, January 25 and 26; third floor, January 31 and February 1; fourth floor, February 4 and 5; and roof slab, February 11 and 12. The brick work was commenced on January 25, and the work was completed as follows: ground floor, bricked in on February 2; first floor, February 9; entire building, February 24. Present indications point towards the completion of the contract well in advance of scheduled time.

During prevailing cold weather the necessary precautions were taken to prevent the concrete freezing. All the materials for the concrete were heated by being placed over perforated pipes, through which steam was forced, the concrete being placed hot. The interior of the building was heated by salamanders, and in order to retain the heat the building was closed in with tarpaulins as the work progressed.

The building will, when finished, be an exceptionally good type of factory construction. The exterior is faced with Laprairie National brick, and the interior is lined with terra cotta, furnished by the St. Lawrence Brick Company, Limited, Montreal, and has a plastered cement finish. The cut stone used was furnished by John Quinlan and Company, Montreal. The floors are hardwood, laid on sleepers embedded in cinder concrete. White enamelled brick is used for the interior finish of all lavatories. All windows are metal, and were supplied by the Steel and Radiation Company, Limited. Darling Brothers, Montreal, supplied the freight elevator, and the Otis-Fensom Elevator Company, Limited, the automatic electric elevator. The iron stairs were manufactured by John Watson and Son, Montreal, Limited. The fire doors were supplied by the McFarlane-Douglass Company, Limited, Montreal.

The construction work was carried out by Anglin's Limited, with the exception of the roofing, which was sub-let to G. W. Reed and Company, Limited, Montreal, the sprinkling system and the electric lighting, the former being let to W. J. McGuire and Company, Limited, Montreal, and the latter to Philip Lahee and Company.

Anglin's Limited have also recently completed several other contracts before the dates specified. Simultaneously with the work described above, the firm put up a three-storey building for the Walter Blue Company, Sherbrooke, in six weeks, or two weeks ahead of time, and have also constructed a five-storey bale warehouse for the Canadian Cotton Company, Cornwall, in a very short time. Another instance is that of the plant of the Canadian Ingersoll-Rand Company, Limited, Sherbrooke, where an extension was finished five days prior to the contract time of ten weeks.



Brickwork completed—Feb. 28, 1916.

Buildings closed in with tarpaulins—Feb. 11, 1916.

Concrete for first floor being poured—Feb. 19, 1916.

Good Roads Congress and Exhibition

Third International and Good Roads Congress Spent Busy Week in Montreal—Delegates from All Parts of Dominion

Judging by the attendance at the Third Canadian and International Good Roads Congress and Exhibition, held in Sohmer Park, Montreal, from March 6 to 10 inclusive, there is a very decided awakening as to the value of good roads. Delegates were present from all parts of the Dominion, although naturally the majority were from the province of Quebec. The delegates included representatives of municipal authorities, contractors, engineers, members of governments and associations, government officials, and experts from over the border.

Throughout the Convention the attendance was exceptionally large, the papers, in English and French, were followed with interest, and the questions asked several of the speakers indicated that the problems dealt with were of real value to the delegates. As will be seen from our report, the papers covered a wide range of subjects; materials, construction, and maintenance being very prominent. Some of the best known experts from the United States were present, and their co-operation was cordially welcomed and acknowledged.

B. Michaud, Chairman

Mr. B. Michaud, Deputy Minister of Roads, Province of Quebec, the President, occupied the chair at the opening, and in welcoming the delegates said the hearty co-operation which they had given at past congresses was bound to be instrumental in carrying out one of the most important objects of good roads, which was the linking together not only of towns and cities, but also the citizens of the Dominion who had a common love for justice and true civilization. He especially welcomed the Ontario and American delegates, and said that the methods which were in operation over the border had been an incentive to the Canadians to carry out similar good work on the roads.

In formally declaring the Congress open, the Hon. P. E. Leblanc, the Provincial Lieut.-Governor, said that he did not know of any two agents greater in their effect upon human progress than good schools and good roads. The Provincial Government was engaged in improving the roads, and it was of special and valuable assistance to them to have such a Congress held so that they might be able to formulate a series of propositions regarding road-building on which could be based further building of roads with the aim of directing its road policy in the interests of the province.

Everybody Interested

Monsignor Roy, on behalf of Archbishop Bruchesi, and Bishop Farthing, both pointed out that their respective churches were interested in the good roads movement.

The Hon. J. A. Tessier, Provincial Minister of Roads, spoke of the benefits that accrued to the farmer, the merchant, the manufacturer, and the whole community through the improvement of the means of communication, and he was sure that the prosperity which marked the province would continue to increase as its highways were improved.

The Hon. J. E. Caron, Minister of Agriculture, said that the good roads policy was first initiated under his department. The Government had gone about its road policy in a systematic way, preparing the public for improvements by a system of education on the value of good roads, and the results had been more than gratifying. The congresses that had been held in the past had been a valuable aid in this respect.

The Hon. Jeremie Decarie, Provincial Secretary, Controller Cote, and Mr. U. H. Dandurand also spoke.

During the session the President read a telegram from Mr. W. A. McLean, Deputy Minister of Highways, Ontario, expressing regret at being unable to be present owing to illness. He declared that to make Canada famous for good roads was a work of patriotism worthy of the greatest support, and requiring the earnest co-operation of every province and municipality from the Atlantic to the Pacific; to that end the Good Roads Congress had his best wishes for success.

At the banquet in the evening, the President stated that the Provincial Government's roads department was always willing to receive road engineers from all over the province, feeling that if they were advocates of the construction of certain roads they were putting forward something that would benefit the country as well as themselves.

Honesty of Public Contracts

The Hon. Jeremie Decarie emphasized the importance of everyone connected with the movement being honest. He would like to see on the order of the day, a paper read on the honesty of public contractors. Every public administration needed workers and they needed experts, but more than that they needed that the contractors should have a conscience that was equal to the task they had to perform for the public. Let their work be honest, whether it was for roads, or public buildings, for the sake of national security. Roads were something common to all; let the contractors be fair and honest to the country that awarded them the contracts.

Mr. S. L. Squire, president of the Ontario Good Roads Association, referred to the importance of a national system of good roads linking all the provinces.

Mr. T. Adams, town planning expert of the Conservation Commission, said the Federal Government should be in closer touch with the roads movement. The Commission of Conservation was interested and anxious to help in every way. Problems of standard road construction and other details needed to be thoroughly discussed, and above all there was the need for system in planning roads. The public authorities were spending a vast amount of money without having a properly considered scheme for the planning of the roads. They had no settled principles on which to proceed, and had no regard to future developments.

The President explained that the province had a plan in its building of roads, that there was a system of trunk roads between cities for heavy and constant traffic, and secondary roads in the municipalities in addition. He pointed out that at the commencement of the Government's Good Roads campaign it was faced with a situation where the need of roads was desperate, and it had to have roads built where they were needed by the citizens. In spite of that handicap, it had linked up the needs of the province in this way with a general plan.

Mr. Adams mentioned that his reference to the lack of planning referred to the cities more particularly—the provincial authorities were carrying out their road policy on a good plan.

Mr. J. W. Levesque, M.L.A., Hon. J. A. Tessier, and Alderman Boyd were among the other speakers, the last named referring to the good work done in Montreal by Mr. Paul Mercier, the city's chief engineer.

The real business commenced on March 7, when the morning session was presided over by Mr. B. Michaud. The first paper was by Mr. J. W. Levesque, M.L.A., who spoke on "Provincial Aid for Road Building." He reviewed in detail the road programme of the Province of Quebec during the last fifteen years, stating that the chief work in road improvement had been accomplished during the last ten years. In 1841 they commenced the decentralization of the laws governing roads with the creation of municipal councils, and from 1845 to 1860 the laws formed the base of the actual system. Mr. Levesque spoke of the excellent work of the Provincial Government in making main highways, notably the King Edward Boulevard, and the Sherbrooke-Derby, Montreal-Quebec, and Levis-Jackson roads. He insisted upon the urgency of provincial governments giving aid to local authorities in making and maintaining roads.

Mr. S. L. Squire briefly discussed the difference between the systems of Quebec and Ontario; in the former the municipality was the unit, and in Ontario the county was the unit. The roads problem was a vital one. In addition to the contribution of 40 per cent. paid to such Ontario counties as went into the scheme, there was one of 20 per cent. for upkeep, the balance being paid by the municipalities. The fact that Mr. W. A. McLean had been appointed Deputy Minister of Highways indicated that Ontario was looking forward to the province taking its place in the sun so far as good roads were concerned. There was a quickening of interest in that province. At a future congress it might be possible to compare the results under the different systems of Ontario and Quebec.

Macadam Road Maintenance

By W. Huber, A.M.C.S.C.E.

Mr. W. Huber, A.M.C.S.C.E., Ontario Highways Department, Toronto, opened the morning session with a paper on "Macadam Road Maintenance." The changing character and the increased intensity of modern traffic have brought about a marked change in the methods of maintenance, and have advanced the question to a position of equal importance with that of construction. Formerly the road builder looked on the completion of the road as the end of his work. To-day it is only the beginning. The present tendency is to consider no road or pavement permanent, for no builder of highways would claim the ability to construct a road or pavement that will withstand the severe strain imposed on it by present-day traffic.

Commence Maintenance

Maintenance should begin on the day the road is opened to traffic. Realizing that a well-built road will require much less expenditure to keep it in good condition than one built to a lower standard, it will be well, before commencing construction, to consider carefully the relation between original cost and the cost of subsequent maintenance. It is well to remember that a moderate increase in the cost of construction may materially lower the annual maintenance charges. It will, for instance, permit an increase of from two to three inches in the depth of stone, and a corresponding increase in the strength of the road, or it will provide an extra inch or two of stone, and in addition a bituminous carpet coat to protect the surface and prevent dust. The latter will result in an improved road, and it cannot be denied that the annual maintenance cost of such a road will be materially reduced.

Annual Cost of Maintenance

The annual cost of maintenance of macadam roads may be quoted roughly as from one to ten cents a square yard, depending on conditions such as the nature and intensity of traffic, the quality of material, character of subgrade, excellence of drainage facilities, and principally the efficiency of the maintenance organization. Efficient maintenance consists of more than keeping the travelled roadway smooth; it must include careful protection to the metal surface, and also the earth shoulders and subgrade from the numerous agencies which tend to destroy them. Such a programme will also include careful attention to the drainage facilities and the improvement of these wherever possible. The use of the split log drag is being emphasized in connection with the maintenance of earth roads. It may also be used with profit on earth shoulders of macadam roads, both in keeping them smooth and maintaining a proper camber and in preventing the growth of weeds.

Destructive Agents

Some of the destructive agencies to which the road is subjected are almost entirely preventable, and may with proper construction be almost eliminated. Of these the chief is probably the action of water and frost in the subgrade. With proper drainage there will be no water under the road, and where there is no water there is no damage from frost. Other agencies, however, such as abrasion and pulverization, caused by horses' feet and vehicle wheels, the shearing action of fast-moving automobile tires, and the chemical actions set up on the weathering of the stone, cannot be entirely prevented, and protection against them consists mainly in minimizing their effects. Much of the wear and damage sustained by roads subjected to increasing heavy traffic are due to the inconsideration of users of the road. To counteract this negligence education will in some cases be necessary, while in others legislation will have to be brought into play. In the former class may be mentioned a tendency to drive in a single track, thereby hastening the formation of ruts. This is frequently encouraged by building narrow roads with high crowns, and a partial remedy is found in widening the metal portion and reducing the crown. In the latter case the assistance of the law to limit the speed of automobiles and the weight and speed of motor trucks would be justified.

When all is said on the causes of road deterioration, and the methods of preventing it, the fact remains that road maintenance consists largely of labor expended on the road surface itself. No matter how good the construction, wear will occur, and it is the chief object of maintenance to take care of this wear before it goes so far as to require repair work. Ruts and depressions will form, especially in a newly-built road which has been laid on an earth subgrade. The second season is usually the road's worst time.

Repairing Ruts

There are two general methods of repairing ruts, either of which will be found effective and inexpensive. The first consists in spiking up the ruts with a road roller, using short spikes, and refilling with new stone from 1 inch to 1½ inches in size, carefully placed and in sufficient quantity to restore after consolidation the old cross-section. This is then rolled and bound with screenings and water, as in the case of the original road. The second plan eliminates the loosening of the road surface, and depends on the use of tar or asphalt to keep the new stone in place. Ruts are first thoroughly swept, the surface painted with bituminous material, new stone placed, and the whole rolled. A small quantity of bituminous binder is then applied, and the whole surface finished with stone chips and rolled again.

Oil as a Maintenance Material

The use of oils on road surfaces is usually considered in connection with the prevention of dust, but the systematic treatment with a good asphaltic oil ranks with the most efficient methods of road maintenance. The most lasting, and generally the most satisfactory, treatment of a macadam surface—particularly when subjected to much motor traffic—is found in the carpet coat. This consists of a thin covering of bitumen filled with stone chips, pea gravel, or coarse sand, applied in a layer of from one-eighth to one-half inch thick. While more expensive than a treatment with light oils, a carpet coat is usually cheaper in the end, owing to the greater durability of a single application and the better condition in which the road is preserved. When properly applied a carpet coat will last, with a small amount of maintenance, from two to five seasons.

Use of a Carpet Coat

The cost of a heavy carpet coat such as described will usually be from eight to ten cents per square yard. Including the cost of maintenance, the actual cost of this form of road protection in ordinary cases will be from two to four cents per square yard. This cost will be somewhat increased on main travelled and suburban roads, in which case it may be as high as from six to eight cents per square yard per annum.

The size of stone chips required will vary with the grade of bitumen used, from coarse sand to ½-in. stone. Whatever size is used, it must be free from dust. Since it is to constitute the actual wearing surface of the road, it should be carefully selected and properly applied. Trap or granite chips should be used wherever obtainable at a reasonable price. First-quality limestone is next in preference, while pea-gravel and coarse sand may also be used.

In order that the benefits of the carpet coat as described may be continued, great care must be taken to keep the surface completely covered. The bare spots must not be allowed to develop, or pits will form. When the bitumen has worn or peeled off the surface, the stone beneath, robbed of its bond, will ravel, and a pit is the result. The scheme of maintenance should provide for a frequent and systematic inspection of all treated roads, and the application of a small quantity of bitumen and stone chips of the same grade as those originally used to any spots where bare stones are showing.

Patrol System

The mention of constant attention introduces the subject of patrol work in connection with road maintenance. The employment of patrol men on the main roads is now quite general, and it remains to have this system extended to cover the less important roads, which must also, in the interests of economy, be kept in a state of first-class repair.

At the first sign of wear or deterioration steps should be taken to repair it in order that the work may be done as cheaply and expeditiously as possible. While attention to the travelled roadway is perhaps the most important of the patrolman's duty, the maintenance of drainage, and its improvement where practicable, are also of vital importance. All side ditches and culverts must be kept open and free from rubbish; weeds on any part of the road allowance should be kept down, guard rails repaired, approaches to bridges and other property promptly repaired.

In efficiency the patrol system has already proved its worth, and the organization of such a system, suited in detail to local conditions, will result in better kept roads at less cost.

The Town Planning Movement

By Thomas Adams

Mr. T. Adams spoke on the subject of town planning. The good roads movement in Canada, he said, was chiefly concerned with roads in rural municipalities. The time seemed to have come when consideration should be given to the need for extending the scope so as to include all authorities and municipalities interested in road transportation in any class of area. The chief trouble in road transportation was perhaps concentrated in the semi-rural areas, where all surrounding traffic radiated towards a given centre. Co-operation between the city and the rural municipality was needed. That was why the city as well as the country districts should be interested in the good roads movement, and why the extension of the scope of the organization was desirable. Referring to the interest the farmer had in good roads, Mr. Adams said that more must be spent in future in getting good roads, and the farmer would have to bear his share of the cost. Up to the present the fault had been largely in the direction of providing too many roads. It had seemed as if they thought by putting road reservations on the map and calling them roads they would become roads without artificial aid. Provincial planning must precede town planning. The farmer in Canada had not yet begun to interest himself in town planning because he had not seen how it affected him. The planning of road widths was required so that more importance would be attached to the principal thoroughfares and less space given and money spent on minor roads in sub-divided districts. They could not afford to give a greater average width to streets than 60 to 65 feet, but they could arrange so that more width would be thrown into main thoroughfares and less width into streets of short length not required for through traffic. The question of width should have relation to the traffic purposes of a street, and farmers would gain as much as any other class from the proper planning of the roads. Whatever standard of width might be fixed in a given area, they could vary the width of the building lines so that no building should be erected nearer than 100 feet to a main thoroughfare, thus enabling them to widen such a thoroughfare in the future if necessary. In most rural municipalities there was still time to plan so as to secure a most sensible adjustment of road widths according to their needs and ability to pay. If 60 feet or 66 feet was a sound minimum for minor streets it was an absurd width for main thoroughfares. The use of road frontage for different classes of buildings should be considered with more care. Manufacturers selected sites in rural areas without regard to the effect of their traffic on roads or the increased burden of taxation they would put on the community. The fixing of certain areas for residences and others for manufacturing was even more important in rural areas than in cities.

After discussing other aspects of town planning, Mr. Adams stated that they should all receive urgent consideration by rural municipalities in town planning schemes. He suggested that the Province of Quebec should pass a compulsory town planning law, giving local authorities power to lay down schemes which would fit in with the general schemes of roads in the province. He also suggested that a department of municipal affairs should be created which should give its especial attention to finance, unemployment, standards of value, planning and construction.

Hot Mix Method of Bituminous Construction

By F. P. Smith, C. E.*

"The Hot Mix Method of Bituminous Construction, Using an Asphaltic Binder," was the subject of a paper by Mr. Francis P. Smith, Ph.B., M.A.S.C.E., M.A.I. C.E., New York, on Tuesday afternoon. Due to the wide variety of bituminous pavements known at the present time, it is always possible to select one type which will satisfactorily answer any given set of climatic and traffic conditions. Bituminous pavements, therefore, come nearer to being the universal ideal type of pavement than any other which have yet been devised.

Bituminous Pavements

Bituminous pavements are smooth, non-productive of dust, almost noiseless, waterproof, non-absorbent and easy to clean. They are capable of sustaining very heavy traffic, and last well under light traffic. They are easy to repair, and offer slight resistance to traffic. Their slipperiness in moist, drizzly weather is largely due to the presence of a thin film of mud. While sheet asphalt will sustain a very heavy traffic, this statement applies more especially to traffic largely composed of quick moving, light to medium loaded vehicles. Wood block and granite block pavement will last longer under dense, slow-moving, heavily-loaded traffic. On account of its smoothness, sheet asphalt pavements are not suitable for use on excessive grades. With a fair amount of traffic it can be used as high six per cent. Where traffic is heavy a three or four per cent. grade is usually considered the limit.

Mineral Aggregate

Depending upon the size of the mineral aggregate used, sheet asphalts may be considered as bituminous mortars or bituminous concretes differing from ordinary mortars and concrete in having a cementing material which is plastic and which may be classed as a semi-fluid or semi-solid. Great care should be taken in the selection of the mineral aggregate and its grading. Pavements produced by these mixtures are to a certain extent malleable and yielding. This quality of flexibility or plasticity makes it necessary to provide a stable foundation. If the foundation is unstable and sinks, the pavement will gradually sink with it, thus forming a depression where water will collect and eventually destroy it.

Hot Mix Bituminous Pavements

Hot mix bituminous pavements differ from each other chiefly in the size and kind of mineral aggregate, the bituminous cement or binder being substantially the same in each case. The coarser the aggregate used the rougher will be the surface of the finished pavement. Generally speaking, the heavier the traffic the finer should be the mineral aggregate used, owing to the fact that the coarse particles are more liable to fracture than the smaller particles. When fracture takes place to any considerable extent rapid deterioration of the pavement will ensue.

Foundation

The character of the foundation required will depend upon the traffic, climate, and character of subsoil and drainage conditions. In cold climates, where the ground freezes to a considerable depth in the winter, and the spring thaws produce unstable conditions in the subsoil, the foundations required must be stronger than in climates where there is little or no frost. A number of different types of foundations have been successfully employed, such as old macadam, broken stone rolled dry or cemented together with some form of bituminous cement, old cobble stone, old brick or asphalt blocks, bituminous concrete, natural cement and Portland cement concrete. Before using any of these types its history, and more particularly its condition in the spring of the year, should be investigated. A sufficient number of test holes should be put down to determine the depth of the foundation, and provision made for a proper under and side drainage. Where depressions are to be filled the road should be cleaned and slightly loosened to ensure a proper bond with the filling material.

Selection of Aggregates

The mineral aggregate constitutes from 75 to 80 per cent. of the pavement, and takes practically all the wear resulting from traffic. It must therefore be se-

* Consulting Engineer, New York.

lected with a great deal of care. It must have clean grains or particles, which should be graded from coarse to fine so as to make the pavement a maximum density. The surface of the grains or particles must be of such a character that the bituminous cement will adhere satisfactorily to them. Sand, gravel, broken stone, or slag, or combinations of these, are the materials generally used in this type of pavement. Sand should be clean-grained, hard, and moderately sharp. Gravel should be clean-grained, hard, and free from adhering clay, with a rough, pitted surface, and gravel containing a large percentage of flinty particles should be avoided. Broken stone should be freshly crushed, preferably in cubicle-shaped particles, the size and hardness required depending upon the traffic. Hard, dense, basic slag is to be preferred; it should be stable when exposed to the weather, and not show any tendency to disintegrate.

Filler and Binder

The filler should be a finely-ground limestone or Portland cement, the latter being preferable for mixtures designed to carry heavy traffic. The bituminous binder, or asphaltic cement, must posses such properties that it will firmly bind together the mineral particles and resist the disintegrating action of traffic and the elements.

Mixing Plant

The plant used in the manufacture of paving mixture is a very important element in the success of the pavement. A uniformly good mixture cannot be turned out by an imperfect plant. Great care must be taken not to overheat either the mineral aggregate or the bituminous cement, as this will injure and harden the latter, while too low a heat will result in imperfect coating of the mineral particles.

The standard sheet asphalt construction of the present day is one and one-half inches of binder and one and one-half inches of wearing surface. The binder should be of a close type—that is, should contain approximately 25 per cent. of material passing an 8-mesh sieve. The binder should, of course, be thoroughly compressed with a steam roller before laying the wearing surface on it. Lack of compression will produce an unsatisfactory foundation for the wearing surface, and binder which is too cold, or made with too hard an asphaltic cement, or an insufficient quantity of asphaltic cement, cannot be properly compressed into a dense, tough mass. Before laying the surface mixture on the finished binder course the latter should be dried and swept clean of dirt, otherwise the laying of the wearing surface will not adhere properly to it. Extra care should be taken to ensure a proper union between surfaces laid on successive days. The joints should be bevelled and freshly cut away, unless the rope joint or similar method is employed. Great care should be taken not to leave any lumps or depressions where the joint is made.

Handling and Care of Machinery

Mr. E. Fafard, superintendent, plants branch, Highways Department, Province of Quebec, read a paper on "The Handling and Care of Machinery." He referred in detail to the plant at Quebec, and to the methods by which the machinery was cared for and protected from the weather when not in use. He outlined the routine of his department, and insisted on the importance of carefully looking after repairs so that machinery could be economically handled.

Road Maintenance, Materials and Methods

By W H. McConnell

William H. McConnell, Chief of the Bureau of Highways and Street Cleaning, Philadelphia, delivered an address on "Road Maintenance, Materials and Methods." A good organization is essential in maintenance, as it is practically impossible to continuously and systematically maintain pavements and roads in first-class condition in an economic manner without good working organization. Maintenance organization and construction organization should not be separated, as separate organizations are apt to shift responsibility as to whether the construction or maintenance division is responsible for any unsatisfactory conditions that may arise relative to the pavement.

Success Depends on Details

It is the intimate knowledge of the details of both construction and maintenance, not considered separately, but in their relation to one another, that is so desirable as a future guide in highway engineering. Every engineer engaged in highway work appreciates the fact that there is no such thing as a permanent pavement for either city streets or country roads; consequently, in addition to the cost of construction, maintenance repair charges during its life must be included in the final cost, and is a most important factor in the selection of a pavement. The main and most perplexing problem of a highway department is, or eventually will be, that of maintenance. If a large percentage of the roads or pavements are already constructed, then maintenance predominates.

Maintenance Organization

It is of course a much simpler matter to cope with this problem of maintenance where the work involved is such that it can be controlled from a central office without delegating the responsibilities to divisions and subdivisions of the organization. This is due to the tendency among the engineers to be lax in attention to details of an apparently simple and routine nature. They are apt to overlook the fact that it is no trick to construct a pavement, as in supervising this work they are simply following a standard well-defined specification; whereas in maintenance work there is no such specification to follow, the success depending upon attention, to a certain degree, to the daily routine and petty details that present themselves. The difficulty of impressing upon the supervising force the importance of this close personal attention to detail in connection with the care of pavements is probably the most important single factor in the operation of a large highway department.

Classification of Work

Road maintenance may be grouped under the following classifications: Routine maintenance, general maintenance, and emergency maintenance. Routine maintenance includes such work as the regular street cleaning in municipalities, or the cleaning of country roads and gutters, or any work that is more or less routine, and should be performed under a definite schedule. The amount and schedule of work and the force necessary to perform it can be determined upon in advance and carried out in a systematic manner under a regular organization, more or less military. General maintenance includes repairs to streets and roads, and involves different characters of work, each requiring special knowledge on the part of those engaged in the actual performance. This branch is generally classified under the three following heads for repair work: (1) Block pavement repairs; (2) Bituminous pavement repairs (mixing method), sheet asphalt, bituminous concrete, etc.; (3) Country roads, macadam, gravel, etc., bituminous surface treatment, and earth road repairs. Further sub-divisions can be handled by those directly in charge of the different classes of work coming under these divisions by training laborers for the particular character of work to which they are assigned.

Emergency Maintenance

The third classification, or emergency maintenance, consists of such work as snow removal and taking care of extensive washouts, both of which require an emergency force, as work of this character must be performed at once, and necessitates putting on an indefinite number of men, depending upon the volume of the work, usually for only a short period of time..

These are some reasons why the maintenance problem is the most difficult one in the highway department. Construction work, in the first place, is usually carried on under contract, and all the cares and troubles relative to the labor situation are put up to the contractor, while in the maintenance work the burden of responsibility is up to the officials of the department, not only in so far as the character of the work is concerned, but also for the control of the organization engaged in its performance.

Maintenance Systems

The general methods employed to maintain a system of highways in good condition are the patrol method and the gang method. The patrol method usually consists of having a man with a team and a repair equipment control and be responsible for making repairs to a certain definite length of highway. The gang method consists of sufficient gangs being employed and equipped with all the materials to make repairs wherever ordered. It would seem that the reporting of the necessity for repair by a special patrol inspector, and the making of these repairs by a specially trained gang, would be the better method.

Mr. McConnell dealt at some length with the methods of bituminous surface treatment used in the city of Philadelphia suburban and country macadam and dirt roads, giving figures as to cost and upkeep for the year 1915.

Road Maintenance in Canada

In conclusion Mr. McConnell pointed out that before long the maintenance problem in Canada would be looming up larger and larger every year. He pointed out the splendid opportunity Canadians had to avail themselves of the experience gained from the failure in other localities where there has been a great deal of highway construction. Summing up, he said it would not be an unfair statement to say that the failures in highway construction have been very much exaggerated. The trouble has been principally, however, the failure to maintain the roads and pavements after they have been constructed.

Cost of New York's Roadways

Mr. Fred W. Sarr, Deputy Highway Commissioner, New York State, read a paper on "The Cost of Maintaining New York State's Highways." After pointing out that the State had paid in 1915 the sum of $4,210,575 under the head of maintenance and repairs, Mr. Sarr gave the following statistics of the average expenditure for maintenance, repair and reconstruction per mile per year for each of seven types of road; 193 miles of gravel roads cost $955 per mile; 2,298 miles of water-bound macadam roads cost $1,055 per mile; 2,387 miles of bituminous macadam, penetration method, roads, cost $510 per mile; 63 miles of bituminous macadam, mixing method, roads, cost $181 per mile; 295 miles of bituminous concrete roads cost $1,050 per mile; 84 miles of first-class concrete roads cost $129 per mile; 291 miles of block pavement roads cost $190 per mile. The 5,611 miles of all types cost $750 per mile.

Legislative Aspect of Road Construction

By A. C. Emmett

Wednesday, March 8

At the first session, on March 8, the chair was taken by Mr. L. Howland, of Toronto. The first speaker was Mr. A. C. Emmett, Winnipeg, whose subject was "The Legislative Aspect Regarding Road Construction." For many years, he said, the road grants made were very meagre, but many provincial governments had now passed Good Roads Acts and the various municipalities could obtain substantial grants towards the carrying out of a definite and well defined plan of road improvement in the country districts. In the Province of Manitoba the Government gave a grant of 50 per cent. of the total cost of construction of all permanent roads, and paid one-third of the cost of dirt roads. No provision was made, however, for maintenance, which was a weak spot in many Road Acts, and the result was that often roads that were well constructed were ruined through the lack of funds to maintain them. There should be a provision in the Acts compelling municipalities to make some provision for maintenance for a period of time equal to that of the bonds which were issued in payment of the construction work.

There was no proper expert supervision of the road work, and to obtain this there must be an absolute change of system. He suggested that the roads of the country be divided into three classes: (1) Dominion roads—main highways—which should be built and maintained at the expense of the Federal Government, the money being paid from the Consolidated fund; (2) main roads but of secondary importance, which should be under the control of the Provincial Governments and paid for by them: (3) municipal roads, which would be feeders, and connected with the two other classes. In Manitoba they had annual split log competitions, supported by the provincial Good Roads Association. The Government this year were giving a special grant enabling the competitions to be extended over an area of 1,000 miles of demonstration roads. There was a difficulty under the Statute labor law in getting work done at the time it would give the best results.

A paper on "Gravel Roads," by Mr. Gabriel Henry, chief engineer of highways, Province of Quebec, was then read.

Highway Bridges

Mr. Lucius E. Allen, C. E., engineer for Hastings County, Ontario, read a paper on the construction of highway bridges. Mr. Allen dwelt on the consideration of the design and construction of highway bridges as a component part in any scheme of highway development.

Bridge structures should be so restricted as to be practically permanent. This requires not only careful designing at the start, but also the judicious selection of the materials to be used. Mr. Allen spoke of the lack of attention paid to securing a good foundation, with its resulting effects, and also on the determination of the size and type of piers and abutments. The balance of the paper was given over to the selection of the type of bridge, its cost, maintenance, and artistic design. It is gratifying to note that great advancement has been made within the past few years in the methods of bridge construction, and when the great highway from the east to the west is begun (as we believe it will be) the construction of these bridges will conform in beauty and permanency with the highway itself. Mr. Allen's paper will appear in full in an early issue of the Contract Record.

Gravel Roads vs. Macadam

By Gabriel Henry

Gravel Roads

"Gravel Roads" was the subject of a paper read by Mr. Gabriel Henry, Chief Engineer of Highways, Province of Quebec. The nature of the top course to be adopted for a road depends more than anything else upon the traffic which it is destined to accommodate. The cost of top courses varies according to their qualities and powers of resistance, and the more solid and durable they are made the more expensive, as a general rule, they are. Outside of cities and trunk roads there are a number of less important roads, generally known under the name of earth roads, gravel roads, and—the most important of them—stone, or macadamized roads, according to the nature of the top course employed. When the soil is of good quality and stoney they are maintained as earth roads. Where there is good gravel, as frequently happens, it is sometimes preferable to make use of it. Yet, even when stone is abundant, it may be advantageous in some cases to prefer gravel—provided, of course, that the volume of traffic does not exceed certain limits.

Drainage

Before gravelling a road, and when all the principal earthworks have been made, and the road straightened, the curves improved, and the bridges and culverts constructed, a perfect drainage of surface water, and the suitable drainage of subterranean water, should be provided. These two conditions are indispensable for any road, no matter what covering may be chosen for it.

Laying the Gravel Covering

There are two principal ways of laying gravel: (1) covering the entire road width between the ditches with one layer, which is given a fixed thickness in the centre, gradually diminishing towards the sides; (2) spreading a layer of gravel over the centre of the road for a determined width with earthen shoulders three or four feet wide at each side to keep the gravel in place. In this case the thickness of the layer is uniform over all its width, or only slightly deeper in the centre. For heavy traffic this latter system is the best, but is more expensive. The average thickness of the layer of gravel depends upon the resistance of the soil and the importance of the traffic. A good gravel on good solid ground may be reduced to an average thickness of four or five inches, measured after settlement. In cases of ground with less power resistance the gravel may be as thick as twelve inches or more.

When stone of a good quality and of moderate size (say four to six inches) is plentiful in the fields, and when it is difficult to advantageously procure good gravel, a foundation of stone may be interlaced between the bed of gravel and the prepared surface of the road. With light traffic this system gives good results, and will prove a good foundation for future macadam.

Qualities of Gravel

The gravel to be employed should not contain too large a proportion of sand, from 20 to 25 per cent. being sufficient. It should not be too earthy, and the small pebbles should be hard and of good quality. Some gravels contain a certain proportion of very soft pebbles, which crush under the wheels of vehicles. Such gravel should be completely rejected—it is not worth the transportation even for a short distance.

Certain gravels bind with difficulty—others more easily. Quartz gravel, from the bed of rivers, is very difficult to bind. However, some silicious gravel, coming from the banks outside of water-courses, bind well with time. When a hard gravel does not bind well a certain portion of clay or marl or limestone dust may be employed by incorporating it with the layer of gravel by the use of a harrow or by any other economical means.

The average distance that it pays to transport gravel depends upon its quality. First-quality gravel which makes a well resisting wearing surface is worth hauling three miles without too much loss. For poorer qualities this distance is much reduced. The cost of labor and of horses also has an influence on the minimum haul to be adopted.

Maintenance of Gravel Roads

The permanent part of gravel roads, that is to say, the ditches, the drains, the foundations, the slopes of fills and excavations, bridges and culverts should be maintained in the same manner for gravel roads as for other improved roads. The surface covering is kept in repair by the use of the split log drag, which should be used often, especially during the first year, to fill in the ruts, to level the surface, and to re-establish the crown. When the covering becomes too thin, and commences to break up from long usage, it is necessary to re-cover it with a sufficient layer of gravel to support the existing traffic without injury. Coverings constructed with hard gravel of good quality will last a long time without the addition of new material, but those which are constructed with sandy or earthy gravel wear more quickly and require more frequent additions.

Unscreened Gravel Roads

Roads with coverings of unscreened gravel are a special type. They must not be confounded with gravel or macadam coverings—that is, those made of screened gravel. They may be utilized in a large measure, and very economically, to improve earth roads, at the same time diminishing the cost of their maintenance. They are very suitable for local roads where the traffic is not very important. The maintenance of these coverings is very easy and inexpensive. It does not call for the use of costly machines or special labor, and the materials are usually close at hand. However, they support an active automobile traffic badly; they are generally dusty in dry weather; and if not looked after they are very muddy in wet weather. They are suitable only for local roads. In a general manner, however, these roads may play a very important part in the improvement of the roadways of the country.

Brick Pavements

By J. Duchastel

Mr. J. Duchastel, engineer of the city of Outremont, read a paper on "Brick Pavements." He said that the main principles governing the construction of a brick pavement were as follows: (1) the proper and efficient character of the sub-soil, most important in this climate; (2) the careful compacting of the sub-soil and the shaping of same to a grade to correspond with that of the finished pavement; (3) the construction of a proper concrete foundation, most necessary in cold climates and in localities where the drainage of the sub-soil was sluggish; (4) the adoption of a cushion layer between the concrete foundation and the bricks; (5) the careful laying of the bricks with the smoothest surface up and lugs laying in the same direction; (6) the thorough rolling of the ungrouted bricks to an even surface; (7) the thorough application of a proper cement filler; (8) the protection of the filler from rapid setting; (9) the prevention of traffic over the new pavement for a period of two to three weeks; (10) the competent supervision of the whole work by efficient men.

Mr. Duchastel then described the process by which a Dunn wire-cut-lug brick pavement was constructed on Laurier Avenue, Outremont, last year under his supervision, by day labor. The main advantage in using these bricks, he continued, was that the joints were all uniform in width on account of the presence of the lugs, which maintained the bricks at an equal distance from one another, and also the fact that the bricks had square corners, and that the joints could be filled from top to bottom at a uniform width without any danger to the grouting being chipped at the surface as in the case of bricks with chamfer corners.

It was well recognized that many failures in brick pavements could be traced to the non-uniformity of the sand cushion or the lack of proper compactness of same. It was claimed by some that a brick pavement should have a cushion so as to keep it resilient under heavy traffic. It was very doubtful to his mind if the sand contained between concrete foundations and the brick pavement had really any elasticity; his opinion was that the brick pavement itself might spring somewhat under the heavy traffic, but the sand cushion would not follow and small air spaces between the sand and the brick pavement might be formed, introducing weak spots which might cause serious trouble later. It had also been claimed that the sand cushion prevented the crushing of the brick pavement under heavy traffic; this idea, to his mind, was not well founded. If bricks well grouted were not able to sustain the load of modern pavement, the sooner they were discarded as paving materials, the better it would be.

The advantages now claimed in using a cement and brick bedding were as follows: elimination of the hazard of the sand cushion during construction, as the pavement would not be injured at any time by rain, the wearing surface, with the exception of the filler, being completed each day. If a rainstorm intervened no damage was done as there was no sand to become saturated and cause worry about rolling the brick surface. Each brick in the wearing surface would be assured a cement bond its entire depth, for if the cement sand should work in the joints, it would set up and prevent the shearing action which tended to crush the top of the brick. There was no chance for the bed to shrink or shift away from the bottom of the brick wearing surface, as the brick was firmly bedded in the cement sand or held in the mortar of the concrete base.

The advantages of brick roadways were as follows: when properly constructed with the right materials they wore smooth without being slippery; they were the most sanitary pavements known, being easily cleaned and absolutely dust proof; they were practically noiseless; they were economical in the long run as they required very little attention and maintenance; they could be cut through when required, and easily repaired at small cost without any cumbersome plant.

Mr. F. A. Snyder, chief engineer, town of Mount Royal, asked how contraction and expansion were cared for. In Philadelphia they put in cement grout expansion joints along the gutter of 1/4 in. to 1/2 in., then one through the centre, and also transversely for 25 feet. When not put in, there were cracks of about 25 feet blocks. Mr. Duchastel replied that they put in expansion joints, for the curb lines, 4 in. high by 1/2 in. thick; no transverse joints were used. He believed the concensus of opinion was that a transverse joint was the weakest part of a pavement, and it was hard to prevent bricks crumbling away at this joint. He thought that any variations of temperature would be disseminated right through.

Mr. Edwards, of Sherbrooke, enquired what was the reason why this particular class of brick was selected. Mr. Duchastel answered that the various points he had mentioned in his paper, together with the fact that no elaborate plant was required were the determining factors.

On the motion of Mr. J. Ballantyne, Mayor of Montreal West, seconded by Alderman Munro, of Outremont, a resolution was passed in favor of establishing national labor bureaus.

Highway Culverts in Quebec

By Alexander Fraser

A paper on "Highway Culverts," prepared by Mr. Alexander Fraser, Highways Department, Province of Quebec, was read. It stated in part:

The limits of application of the word culvert is not exactly established. In the following few words I will apply the word somewhat arbitrarily to all work of whatever type, from the circular culvert of 12 in. diameter, to the bridge or culvert of 8 ft. spans. In the province of Quebec these culverts are considered as an integral part of our roads and their permanent improvement is made in accordance with the plans and specifications furnished or approved by the Department of Roads. The construction of bridges of greater dimensions is generally carried out under the control of the Department of Public Works. But here again, naturally, when the question arises of making of a work of a permanent character on the probable line of a proposed provincial road, there is an understanding between the engineers of the two departments as to the location of the bridge in view of securing the best possible alignment. As the culverts constitute a permanent part of the improvement of our roads and their cost forms an important item in the total cost of that improvement, special attention to them is therefore necessary, together with method and economy.

On our provincial roads in the province of Quebec the average cost of the permanent culverts from 12 in. diameter to 8 feet span has varied from $800 to $1,500 per mile.

Circular Culverts.—In the province of Quebec we make circular culverts of 12 to 36 in. diameter on our provincial roads. All the circular culverts are of concrete and of all the other circular culverts made in the province a little more than two-thirds are of concrete, the rest being of corrugated steel, iron or vitrified clay pipe.

I believe that the concrete culverts will give the most satisfactory results if the materials used and the methods of construction are those commonly known as the best.

Concrete to-day, although it may still improve in the future, has passed the experimental stages as to the certain results expected. But our manufacturers of concrete pipes, at least as far as the province of Quebec is concerned, do not all use the best methods of manufacture. Fortunately, a movement is now under way with a view to the formation of an association of all the concrete pipe manufacturers like that existing in the United States, whose main purpose will unquestionably be to put on the market a more uniform product and of the very best quality.

The quality of the pipes is not, however, the only consideration that can assure to the culvert its permanency and its efficiency. It is also absolutely necessary that they are put in place with care if we want them to give good results. The need of intelligent and experienced foremen is greater than we are commonly let to believe, because it is often very expensive to repair a culvert when the roller has passed or the pavement is sometimes nearly finished, breaks or dislocations are noticed.

A culvert has two main purposes to perform—to provide a safe passage to the traffic and to secure a perfect drainage while protecting the road. To provide a safe passage to the traffic we will have to give the culvert a length equal to the width of the travelled way. This is specially important at the intersections of the roads. The addition of one or two pipes to a culvert in order to provide an adequate length can be done in most cases without increasing the cost of the culvert. The alignment of the culvert must be so as to provide a rapid flow of the waters. To that end the introduction of two or four right angles in the lines of a ditch for the laying out of a culvert, as it frequently happened in the old structure, must be avoided. If the line ditch at the upstream and downstream sides of the culvert happens to be on two different lines of not more than 25 feet apart we generally prefer to place the culvert at a certain angle with the centre line of the road, so that its two ends will meet the two lines of the line ditch at each side of the road.

We must specially care not to place the culvert at right angles or nearly so with the centre line of the road and between the two line ditches. If those two ditches were too far apart, it will be better then to place the culvert on the produced line of the upstream and ditch. By so doing we will get one of the two angles and we will reduce to the minimum the underminings which may be caused during the flooding season.

The trench to be excavated for the culvert ought to be at least two feet wider than the external diameter of the sheets to be laid. If the trench has but a width equal or nearly equal to the external diameter of the culvert it will be difficult to sufficiently ram the earth in the lower part, and the latter will seldom be rammed at all. Consequently, the culvert will not be held firmly in place, and when the rolling starts it will tend to move, and the joints will be dislocated.

Important Details

We must be careful to give the bottom of the trench a concave form suitable to the sheets to be placed so as to insure to the latter a greater bearing surface and of a more uniform resistance. The minimum grade of the bottom of the trench will have to be at least 5 in. per 100 ft., and be made so as, when the culvert is in place, to allow the water to flow freely on a regular grade inside as at the upstream and downstream ends. It is very important to have all the joints cemented on both sides, so as to avoid all washouts and caving in of the soil around the culvert.

A very important detail, which is too frequently put aside in practice, is to make the backfill by parallel and successive layers of not more than 6 inches thick and to perfectly ram each of them. The backfilling material must be carefully selected. It is necessary to pave the bottom of the ditch at the upstream and downstream end of each culvert, especially if, on account of a steep grade or of a break in the profile, there is danger of erosion occurring.

We must be careful to leave at least 12 inches of earth over the culvert, especially if we have to deal with vitrified clay, corrugated steel, or concrete pipe. If it is not possible to give the 12 inches, it will be better to lay a cast iron pipe culvert.

Other Descriptions of Culverts.—Most of the remarks made with regard to circular culverts apply to the other styles of culverts of plain or reinforced concrete, quadrangular culverts, slab culverts, with or without beams, and arch culverts. A control which cannot be exercised in the case of circular culverts, control of the mixture, of the quality of materials and of all the other details in the making of concrete, can here be exercised freely. To this end it is important to permanently keep a competent foreman or inspector on the work being carried out. His duty should not be limited to the supervision of the proportion of the mixture and the time of mixing each batch.

The width of the roadway on these culverts should be of 18 feet on local roads, and of 24 feet on trunk roads. The bed of the creek where the culvert is located must be paved with dry stone, if on account of the grade, it is exposed to erosion.

The alignment of the road in view of the location of these culverts must be made in a judicious way. Except where unavoidable, they should not be located on curves, especially on short radius curves. Too frequently culverts have been located to suit the creek, and not enough consideration has been given to provide a judicious alignment satisfactory to traffic.

Mr. A. E. Cunningham, representing the Lethbridge Board of Trade, alluded to the importance of highways to the country, which, he said, would be understood when it was remembered that practically every bushel of Western Canada's 300,000,000 bushel yield must now pass over some highway in its first stage of transportation.

The session concluded with an illustrated lecture by Mr. J. S. Crandell, of the Barrett Manufacturing Company, and formerly Professor of Highways at the Pennsylvania State College, on the Use of Refined Tar on Roads, both in penetration and treating systems.

Thursday, March 9

The opening paper of the first session on March 9, when Mr. B. Michaud presided, was by Major W. W. Crosby, C. E., consulting engineer, Baltimore. Prior to the reading of the paper, the chairman discussed at length the various types of roads in the province of Quebec, including natural, sand, gravel, macadam, concrete, and bituminous. He spoke of the advantages and disadvantages of the different types, their cost, and methods of construction. So far they had not found either in this country or in the United States a road which might be described as final in regard to perfection, but they were making progress along that line.

Mr. F. A. Snyder, referring to the dirt road, urged the importance of keeping the drainage ditches open. They ought to start work in the fall, and enable the water to run off quickly. Places where there were bad and spongy spots should be replaced with good hard material. He advocated the use of light instead of heavy machinery; the work would go further and the cost would be less. He would like to see the road drag more largely used, and had obtained very satisfactory results from a light road grader. The patrol system was to be preferred to the gang system. On no account should roads be allowed to deteriorate; engineers must keep up maintenance all the time.

Mr. C. D. French, of the Kinney Construction Company, referred to his experiences in constructing the Montreal-Quebec highway. Macadam, he said, cost practically the same as concrete, owing to the expense in the foundation of the sub-soil. Immediately after the building of a macadam road it was necessary to commence repairs, but this was not so in the case of concrete roads. After four months' wear of macadam roads, he found there were sags, and that, despite special precautions for the pipes and culverts, defects developed; in the concrete roads, however, there were no depressions whatever.

Road Drainage and Foundations

By Major W. W. Crosby

"Road Drainage and Foundations," was the subject of a paper by Major W. W. Crosby, consulting engineer, Baltimore. Drainage referred to is that provision made for taking care of water so as to improve the foundation of a road or protect it from injury. Foundations may be divided into two classes—natural and artificial. A natural foundation must ultimately be that portion of the earth's crust on which the beginning of the artificial structure rests. It may be some distance below the surface of the roadway, and be separated from the latter by various layers of construction, including an artificial foundation.

Requisites of a Good Foundation

The requirements for a good foundation are (a) that it shall be capable of supporting under the most adverse conditions likely to surround it the loads coming on it; (b) that it shall be homogeneous and uniform to an extent sufficient for the probabilities of the case; and (c) that the above qualities shall be obtainable at a minimum cost in the long run. There may be need, however, for considering the question of the probable permanence of the supporting power of the material under such conditions as may later arise. For instance, the incompressibility and supporting power of sand may be extremely high as long as there shall be no chance for the sand to flow. The tendency of the sand to flow may be tremendously increased by the presence of water. Precautions should be taken by provision for drainage to prevent the existence of such dangerous conditions. Drainage thus enters into consideration of the foundation, if for no other reason than to provide means that water shall not, by its advent into the foundation, injure the supporting power of the latter seriously. Drainage provisions should not be merely sufficient for the conditions existing at the time, but should be ample to take care of any conditions that may seem possible of occurrence.

Most natural materials can be made into sufficient foundations for pavements if they are of the so-called "mineral kingdom." The question, however, as to whether to use the natural mineral material in place, or whether to substitute something else for it, is often mainly an economic one. Modern tendencies are towards the more severe use of roads and streets, with greater demands on their foundations than heretofore, and these tendencies must be properly met.

Artificial Foundations

Artificial foundations include all layers of foreign material not naturally found in place, and specifically provided for the purpose of interposing a layer of some sort between the natural material and the pavement surfacing. Under this head will come sand, gravel or similar material, old or new macadam, old or new paving, as well as concrete slab. A layer of sand or gravel as an artificial foundation is used to good advantage on subgrades whose supporting power is relatively weak. Further advantages of such a layer are that it assists in providing drainage and in increasing the stability of the subgrade. Well-compacted macadam is high in its supporting powers and in its stability in place. The difficulty of using an old artificial foundation is to get it surfaced sufficiently even so that the final surface shall be smooth, and at the same time have the same degree of requisite uniformity and thickness.

Concrete Foundation

Apparently the highest type of artificial foundation is the concrete slab. The power of such a foundation to distribute widely stresses coming through it is very high. Little has been actually determined as to its distributing power and its ability in pavement foundations to carry indefinitely beamlike strains. Cement concrete slab, however, has proven its ability to aid weak subgrades to carry satisfactorily continuous heavy traffic. Too often the practice has been to consider no care necessary in the selection and preparation of the subgrade where a concrete slab was to be interposed between it and the pavement surface. The contrary should be the real practice.

The standard concrete foundation pavement in America is six inches in thickness, and a greater thickness has been advocated as desirable, and even necessary, under certain extreme traffic conditions.

Surfaces and Materials for Roads

By Col. Wm. D. Sohier

Col. William D. Sohier, Chairman of the Massachusetts Highway Commission, gave an interesting paper on "Selection of Surfaces and Materials for Roads as Governed by the Traffic that they must carry." Col. Sohier's paper included extensive statistics on traffic in different parts of the state, and the increased use of the motor vehicles.

The selection of the best materials and the proper use of those materials in the construction of a road surface that will remain in good condition for a reasonable length of time, and will economically carry the traffic that uses that particular road, is the most important as well as the most difficult problem which the highway engineer and road builder has to solve. Often, due to the lack of funds, he cannot build the class of road he wants to, or use the materials which he knows would give the best results. The engineer therefore has to take into consideration every time the money available, the best materials that can be secured within a reasonable distance of the road, and the best method of using these materials in constructing the road.

In the near future, no doubt, the heavy traffic of our roads will increase greatly, and will be carried by motor truck instead of wagon. Road builders must consider, therefore, not only the traffic that is now using any given road to be built or re-surfaced, or even maintained, but also what the traffic will be in the near future, and how much it will increase, and what changes will come in its character and volume. Col. Sohier dwelt at some length on the traffic census of roads in Massachusetts since 1909 up to the present, giving tabulation of the increases and changes in traffic in both motor and horse-drawn for the years 1909, 1912, and 1915; figures which are very interesting, and show conclusively that our highways must be strong enough to withstand heavy motor-truck traffic. He also dwelt with the pleasure traffic around Boston and metropolitan parks in the state. He also showed the increase in travel caused by building new good roads, quoting as illustrations the increased traffic on the Newburyport Turnpike, the Mohawk Trail, and other shorter popular pleasure drives about the state. Motors are always trying to find an easier route and to see a new country wherever the roads are fairly decent. When a really good road is built they come in hundreds and thousands, especially if the scenery is attractive.

Road Practice in Massachusetts

Dealing with the width of the road surface, Col. Sohier said that the standard practice for over fifteen years had been 15 ft. with a 3-ft. shoulder on each side, but with the increased motor traffic the present practice was 18 feet in width of hardened surface, with 21 feet width on all curves. Col. Sohier spoke of the present method used in road construction in Massachusetts, the selection of the type of road and the materials used, giving figures and statistics of their experience in road building in that state. Speaking of the growth of the better road sentiment in Massachusetts in the last eight years, he said that at present the Massachusetts Highway Commission is spending about three million dollars a year for construction and maintenance of State roads, while eight years ago they were only spending some $600,000 a year. In conclusion Col. Sohier pointed out that the best argument for a road is the road itself: "Get busy; build the best roads you can afford to build; locate well; secure sufficient width of location; drain it well, and grade it with proper materials; then keep the road constantly shaped and always in a passable condition. Show what a little care, attention, and money will do. One mile of good road in good order is a better argument for good roads, and will produce more votes and more money and more Good Road advocates in one year, than all the conventions and learned speeches that have ever been held and delivered in the last thirty years." In closing Col. Sohier mentioned the great pleasure it had been to him to attend the Conference and meet with the several engineers there—particularly Mr. McLean and Mr. Michaud, who are well-known in the States, and whose advice on questions affecting Good Roads is always valuable.

Mr. Snyder took up the question of road and foundations. In most cases, he said, it paid to put in side ditches to keep the water away from the roads. He advocated very strongly underdraining, this being an economical expenditure. In planning a new road, it was wise in the spring to carefully go over the route, which would minimize trouble when the work was commenced in the summer.

Mr. Paul Mercier, chief engineer of the city of Montreal, presented an illustrated paper, giving particulars of the civic departments, having special relation to the engineering, sewerage and road departments.

Concrete Roads and Pavements

By P. W. Wilson, M.A.S.C.E.

Mr. P. W. Wilson, M.A.S.C.E., consulting engineer of Philadelphia, read an interesting paper on "Concrete Roads and Pavements." The two most important items to be considered in road building are the selection of the type of road to build and the raising of the money to build such roads. In selecting the type the first cost of the road is a matter of consideration, and in many localities those having to do with the road construction have permitted their anxiety to stretch the amount of money available over as great a mileage as possible, and caused them to lose sight of the fact that the road was being built on borrowed money and that the time would come when the municipality would be forced to pay the money back.

The type of road should, therefore, be moderate in first cost—not necessarily cheap—and further, of the type of construction where the need of additional money accruing from taxes would not have to be expended in maintenance, but could be expended from year to year in extending the road system.

The present trouble seems to be to build too great a mileage of an inferior grade, rather than building less mileage of greater permanence, which would not require continuous repair. For those having nothing but dirt roads it seems a big jump to pass to hard-surfaced roads from a cost of practically nothing for the dirt road to a cost of about $10,000 per mile.

Items entering into the construction of the road are the consideration of cleanliness, non-slipperiness in wet weather, and dustlessness. These several conditions seem to be very well fulfilled in a concrete road.

The permanent character of concrete roads is best illustrated by the condition of the road after several years. They require an extremely low maintenance cost. Roads in use for over twenty years have been maintained for less than $30 per mile per year. In no case on record has the maintenance charge exceeded $50 per mile per year.

In building a concrete road great care should be taken to select the aggregates to secure the best results. Also, careful attention should be given to the question of drainage. The majority of the cracks in concrete roads are produced by the lack of proper drainage and the lack of proper preparation of the foundations, rather than from the effect of expansion and contraction. In selecting the materials the sand should be well graded in size from fine to coarse to give a minimum of voidage, and the coarse aggregates should be hard, durable, and clean, since they are depended upon to take the wear in any class of road construction. Bank-run materials should never be used without first separating by screening its coarse and fine aggregates so that the exact amount of each may be known.

In finishing the surface of a concrete road wooden floats are used to give a road a rough finish. As thin a coat of cement and sand as possible should be drawn to the surface, since this coat under traffic rapidly disappears, leaving the coarse aggregates to take the wear. The most common mistake in finishing a concrete road is in overfloating. Green concrete should not be exposed to the hot rays of the sun.

The time of opening a concrete road to traffic varies to a great extent with the time of the year the road is built. A road built in cold weather should be kept closed to traffic a much longer length of time than one built in warm weather.

The cracks which appear in a concrete road are due in almost every case to lack of drainage or the proper preparation of the sub-base. These cracks are, without doubt, unsightly, but they are not a serious detriment to the road provided they are properly cared for. The use of reinforcement is suggested as an insurance against poor drainage, and the lack of proper compacting of the foundations.

One of the most satisfactory tributes which can be paid to the concrete road is that where municipalities have one laid they continue to lay more of them.

Mr. W. A. Magor, in a brief paper, advocated the construction of a road from Montreal to Ste. Anne de Bellevue, giving a thoroughfare from one end of the Isle of Montreal to the other.

Winnipeg Next Year

The reading of three papers, the election of officers, and the selection of Winnipeg as the next meeting place of the Convention, comprised the proceedings at the concluding session on March 10. Mr. B. Michaud presided.

Roadways Legislation

After a paper by Dr. E. M. Desaulniers on "Legislation on Roads in Canada before Confederation," Mr. Arthur H. Blanchard, Professor in charge of graduate course in Highway Engineering, Columbia University, spoke on "Recent Developments in the Course of Construction of Bituminous Macadam and Bituminous Concrete Pavements." He dealt with the two types of bituminous pavements and gave details of construction and design. Three points were to be considered in connection with bituminous macadam pavements—the quality of broken stone to be used, the sizes of broken stone employed, and the character of the bituminous material used. The broken stone to be employed and the bituminous materials to be used were most important factors in the construction of bituminous concrete pavements or paving built by mixing methods. Professor Blanchard referred in detail to many classes of bituminous concrete and bituminous macadam pavements, and advocated the more general use of alternate specifications, instead of blanket specifications, in reference to various types of bituminous material. Under the former contractors had to bid on specific materials, instead of leaving it to them to adopt one of the many kinds of material on the market. By means of slides, Professor Blanchard gave many practical hints on the construction of bituminous roads. One slide showed a specification, in which there was a clause to the effect that the work should be carried out to the satisfaction of the engineers. This kind of specification, said the speaker, did not meet with his approval, although the particular job was carried out satisfactorily, owing to the broad-mindedness of the engineers and contractors. The matter of seal coat was of great importance, and under present conditions should always be used.

On behalf of contracting and supply firms, Mr. M. J. Stack, of Montreal, presented Mr. Michaud with a gold mounted cane, stating that the gift was an expression of their appreciation of Mr. Michaud's services. The President, in replying, stated that his work had been a pleasure, and he intended to do what he could for the progress of the good roads movement.

Creosoted Wood Blocks

Mr. A. F. Macallum, city engineer of Hamilton, read an interesting paper on the use of creosoted wood blocks in street pavements. Mr. Macallum has had a wide experience in wood block paving and is satisfied of their value. His experience is that where traffic has the choice between wood block and other pavements that the former is used to a much greater extent. The first cost of wood block pavement is higher than most other paving materials, averaging in the city of Hamilton from $2.85 to $3.00 per square yard, exclusive of grading. However, when its cheapness of maintenance, ease in cleaning, low tractive resistance and durability, are taken into consideration it will in general prove ultimately cheaper than a roadway of lower first cost. Mr. Macallum's paper will be treated more fully in a later issue.

Highway Bridges

"Highway Bridges," particularly those in the province of Ontario, were exhaustively discussed by Mr. Geo. Hogarth, chief engineer, Highways Department, Province of Ontario. Mr. Hogarth referred in detail to various types of bridges, from those in rural municipalities and sparsely populated districts to those in large cities. Methods of construction and material were enlarged on, and some defects in the old types pointed out.

Mr. J. Duchastel, President

This concluded the reading of papers, and the report of the nominating committee was then taken up. This report recommended the following names as officers for the ensuing year, the report being adopted: Hon. Presidents: Messrs. U. H. Dandurand, Montreal; W. A. McLean, Toronto; B. Michaud, Quebec; O. Hezzelwood, Toronto; President, J. Duchastel, city engineer, Outremont, P. Q.; vice-president, S. L. Squire, President Ontario Good Roads Association; secretary-treasurer, G. A. McNamee, Montreal; committee: Messrs. A. E. Cunningham, Lethbridge, Alta.; A. C. Emmett, Winnipeg; Howard Pillow, Montreal; J. A. Sanderson, Oxford Station, Ont.; R. S. Henderson, President Manitoba Good Roads Association; T. Adams, town planning expert, Ottawa; E. M. Desaulniers, M.L.A., Chambly County; J. W. Levesque, M.L.A., Laval County; Paul E. Mercier, chief engineer, city of Montreal; A. F. Macallum, city engineer, Hamilton; George Hogarth, chief engineer, Highways Department, Ontario Provincial Government.

On the motion of Mr. Emmett, representing the Manitoba Government, seconded by Mr. Cunningham, it was decided to hold the next convention in Winnipeg. The conventions have hitherto been held in the East, and the idea is to give them a wider scope, and to stimulate Western interest in the movement.

A vote of thanks to the retiring president, Mr. Michaud, concluded the proceedings.

Exhibition of Machinery and Road Supplies

As compared with the previous exhibition of machinery, road supplies, materials, etc., the one just concluded showed a considerable diminution in heavy machinery, but a more diversified number of road materials. The booths, including those of "The Contract Record and Engineering Review," and other trade papers, were tastefully decorated with red bunting, flags, and palms, and well furnished, and as the building was particularly well lighted, the effect was both business-like and artistic. Each booth was distinguished by a large card placed at the end.

Canada Cement Company, Montreal.—Almost the entire stage of the hall was occupied by the exhibit of this company, being the largest amount of space taken by any of the exhibitors. In the front of the stage was a large ornamental concrete fence made by Mr. De Grelle, of Montreal, and behind was a model concrete roadway, 30 feet long by 16 feet wide, showing the method of construction. The road was reinforced with the Kahn system of the Trussed Concrete Steel Company of Canada, Limited, and with Clinton fabric reinforcement manufactured by the Pedlar People, Limited. The Canada Cement Company had on view a number of pictures of concrete roads built through the Dominion.

The Pedlar People, Limited.—The exhibit of this company, occupying a portion of the stage, was a little out of the ordinary. One feature was, as above mentioned, Clinton fabric reinforcement in a roadway built by the Canada Cement Company. The Pedlar People had on show ferro dovetail plates for bridge floor reinforcement, rib fabric lath for reinforcing floor slabs, roofs, and partitions, and also Toncan metal culverts.

Paterson Manufacturing Company, Limited, Montreal.—In addition to many samples of Tarvia, this company showed a large number of illuminated pictures of roads in Quebec, Ontario and the United States treated with their well-known specialty.

Dunn Wire-Cut-Lug Brick Company, Conneaut, Ohio.—This firm have now 29 companies, operating 46 plants, under license manufacturing this class of brick. The brick is extensively used in Outremont, Lachine, Verdun, and Toronto. The exhibit consisted of wire-cut-lug bricks laid up, this brick being 4 inches in depth, 3½ inches in depth, and 3 inches in depth.

Asphalt and Supply Company, Limited, Montreal.—Quite a large show was made of this company's products. There were samples of Fluxphalte with views of the King Edward highway covered with this material, a job which will be finished this season. Besides Fluxphalte, there were samples of Eagle asphalt and asphaltic concrete, together with photos of Mexican oil wells, including the largest well in the world.

Canadian Fairbanks-Morse Company, Limited, Montreal.—In point of numbers, this company had the most extensive exhibition of machinery on view. Two machines were loaned to the company by the city of Outremont—a combined tank wagon and distributor, and a distributor, the latter being used for the penetration method on loose macadam roads. Three Wettlaufer mixers, a crusher, a kerosene road roller by the Ohio Tractor Company, a Star reversible traction wagon and a contractors' dump wagon (both by the Glen

Wagon Company), a Maney four-wheel scraper, horse scrapers and road ploughs, and a contractors' gasoline-driven pump, were also shown.

Canadian Tar Products Company, Limited, Montreal.—This concern is a comparatively new comer in the Canadian field. Its product is known as Tarmac, a preparation used as a binder for macadam roads and also for the re-surfacing of macadam roads. The company had also on exhibition paving pitch for block paving. The products are purely Canadian, and are manufactured from Canadian produced tar. The company is operating at Ville La Salle, near Montreal, a very complete tar distilling plant, one of the latest on the American continent.

The Philip Carey Company, Montreal.—At this booth there were samples of the Carey Elastite expansion joint—"The Sandwich joint"—which consists of a heavy body of special asphalt compound sandwiched between two layers of a special grade of asphalt-saturated wool felt,—the whole being firmly bonded together by a combining process of the company. The feature of this joint is the increased compressibility secured by increasing the volume of the asphalt compound, and keeping it in a solid body instead of distributing it throughout the joint in several thinner layers.

Imperial Oil Company, Limited, Montreal.—The products, as shown, were those which will be made in the new plant of the company now being constructed at Montreal East at a cost of a million and a quarter dollars. They will be manufactured from the finest Mexican oil which will be brought by tank steamers to the port. The exhibit consisted of asphalt for hot mix pavements—sheet asphalt and asphaltic concrete; asphalt binders, for the laying of penetration asphalt pavements; asphalt binders for re-surfacing macadam and gravel roads; light asphalts for re-surfacing and dust prevention on macadam and gravel roads; asphaltic liquids for dust prevention; and block filler for sectional pavements—wood block, brick and granite setts.

Creosoted Block Paving Company, Limited, Toronto.—Here were shown paving blocks, bridge floors, factory floors, and creosoted lumber. The company have a fine factory at Trenton, Ont., and their products cover a wide range in their particular field.

J. B. Dore and Fils, Laprairie, P.Q.—Road machinery is the specialty of this firm, who make road crushers, rock crushers, steam road rollers, road graders, portable and traction engines, scarifiers, etc. They had on show a "Little Ideal" road grader, which can be operated with two or four horses. They also had specimens of cast iron culvert pipe.

Elder Ebano Asphalt Company, Limited, Montreal.—At this stand there were samples of asphalt macadam, mastic asphalt for sidewalks, rock mastic asphalt, Paterson and Shawmut paving blocks, Norway pine creosoted blocks, and granite blocks—a very comprehensive exhibit.

Sawyer-Massey Company, Limited, Hamilton, Ont.—The company exhibited a steel reversible road grader of which there are over 2,000 in use in Canada; a portable rock steel frame crusher with folding elevator; and a double cylinder steam road roller with all-steel gears, differential gear, and renewable gear rims. The latter is, it is claimed, the only steam road roller built in Canada which is equipped in this manner.

The Montreal Concrete Works Company, Limited, Montreal.—The company showed numerous samples of their different styles and sizes of concrete pipe made at their plant at St. Francois de Sales, Que.

Canada Ingot Iron Culvert Company, Limited, Guelph, Ont.—Specimens of their rust-resisting "Armaco" culvert pipe in sizes 8 in. to 84 in., were shown. The company claim this pipe is particularly adapted for permanent highways as it will not break from traffic or frost.

Kinney Manufacturing Company, Boston and Montreal.—A combination power-operated kettle for bituminous materials was on view. It will heat for any temperature desired. The material is put on under pressure through a hand nozzle or spray pipes. The other exhibits were a horse-drawn distributor for light oiling or dust laying, and a portable loading outfit from tank cars to distributors. In Canada the company is represented by Mussens, Limited, Montreal.

Quinlan & Robertson, Limited, Montreal.—This firm of contractors had on view a large number of photos, showing progress of various road, conduit, canal, railway, etc., contracts carried out in all parts of the Dominion.

Rigaud Granite Company, Limited, Montreal.—Exhibit demonstrated methods of constructing "Durax" pavement; samples of "Durax" paving, which is "Made in Canada," were also shown. It is claimed that this type of pavement is used extensively in the United States and Europe.

Aztec Oil and Asphalt Refining Company of Canada, Montreal.—A display was made of samples of Aztec liquid asphalt, road binder, and refined asphalt. These are natural asphalt products, and are made from Mexican raw material.

J. H. McCarty & Company, Montreal, and Rene Talbot, Quebec.—A working model of a Champion crusher, made by the Dominion Road Machinery Company, Limited, Goderich, Ont., was shown in this booth, together with a gasoline fire engine manufactured by the Waterous Engine Works Company, Limited, Brantford, Ont. Besides these, there were photographs of a complete line of road making machinery, street cleaning machinery, and fire apparatus.

Comet Motor Company, Limited, Montreal.—Exhibited a New Packard worm driven truck and a Chalmers "30."

T. A. Morrison & Company, Montreal.—Exhibit showed samples of "Tamco" Banc Rouge Trap for macadam roads; also samples of river sand and Milton pressed brick.

Stack and Leger, Montreal.—Photos of various road and paving contracts carried out.

G. Aybram, St. Emile Junction, P.Q.—Exhibition consisted of samples of Silex gravel sands.

Kennedy Construction Company, Limited, Montreal.—Various photos of concrete roads built by the firm in the vicinity of Montreal were on view.

Trussed Concrete Steel Company of Canada, Limited, Walkerville, Ont.—Featured Kahn road mesh, Kahn armor plates and Kahn curb bars. It is claimed for the Kahn road mesh that it is extremely rigid, easily placed and will stay where placed without being staked. Kahn armor plate is used in protecting edges of contraction joints, and as it is made of dead soft steel it wears down with the road. Kahn curb bar is used to protect the wearing edges of concrete curbs.

The Province of Ontario loaned a number of models showing the construction and materials of various types of roads, while the city of Montreal displayed a number of plans and also loaned some road machinery.

Methods and Costs of Garbage Disposal

Different Systems of Final Disposal Employed by U. S. Cities — Incineration and Reduction — By-Products — Methods of Financing Cost

THE State Bureau of Municipal Information of the New York State Conference of Mayors and other city officials—W. P. Capes, director —have recently issued their report No. 52 on "Methods and Costs of Collecting and Disposing of Garbage in Cities." This report describes the different systems of collection and disposal now used by the larger cities in America, points out the factors which affect the cost, and gives the opinion of experts for and against the various systems. All the information has been recently collected and published as a guide for those cities desiring either to establish systems or to improve existing ones. The following extracts covering the disposal of garbage are taken from the report:—

The methods that may be adopted by a city for the disposal of its garbage are as follows:—feeding to swine, dumping on land, dumping into large volumes of water, disposal by sanitary fill, burial, incineration, and reduction.

In selecting its disposal system a city should at the same time consider its collection system. Some cities collect and dispose of their garbage by contract, others collect by contract and dispose of it themselves, or vice versa, and still others have all the work done by city employees.

Feeding to Swine

Most of the smaller cities in this country dispose of a part or all of their garbage by feeding to swine. The others either collect their garbage by contract and sell it or give it to farmers or those operating piggeries, or maintain a municipal collection and sell to a contractor who maintains a piggery. The necessity for sterilizing the garbage before it is fed to hogs is disputed.

Kansas City, Providence, Denver, and other cities have their garbage fed to hogs, with the uniform result that the cost of removal is reduced to some extent to the city and that the contractor, according to his business capacity, is able to make more or less profit from the feed so obtained. There is no danger in this system under proper handling. Any danger to the hogs can be prevented by prompt handling of the garbage to prevent unnecessary fermentation, and by the use of hog cholera serum to prevent disease. The proper cleaning of the pens, if in the city, eliminates any danger to man. There should be some method of sorting the garbage before feeding it to pigs so that the stale garbage may be discarded and buried or burned. Some places disinfect it by boiling in large cauldrons before feeding. In such cases the cooked garbage is commonly used only as a base for the feed given to the pigs. The method is a most profitable one and warrants consideration in small cities where isolated farm sites are available.

Dumping on Land

It is the concensus of opinion in all reports and of all experts that this method is objectionable, especially where there is a large quantity to be disposed of. A long haul is necessitated by the location of the dumps at a remote distance, where the decomposition of any part of the refuse will not be offensive to neighboring property owners. When the garbage is deposited in sufficient quantity offensive odors due to fermentation may create a nuisance. Unless special attention is given to the treatment of these dumps, the method will not be found desirable. A thorough mixing of garbage with ashes and rubbish will prevent the nuisance and the fires that are otherwise liable to occur, creating odors and nuisance from the smoke and unconsumed gases. This method is one that cannot be defended either from an aesthetic or sanitary standpoint. The dumps become an ideal breeding place for flies.

Dumping in Large Bodies of Water

Only a few cities use this method. In most places where it has been tried, it has been prohibited because the material is washed on the neighboring shores.

Disposal by Sanitary Fill

This method is practised by some cities, among them Seattle, Davenport, and New Orleans, which report its success. It is being given more serious consideration than heretofore by several large cities. The method is different than that of burial, in that it is carried on by filling excavations, vacant low lying ground and natural ravines.

The garbage, rubbish and ashes are dumped and then mixed with sufficient earth to insure oxidation and thorough digestion of the decomposing wastes. The activity of the bacteria of the soil breaks down and mineralizes the organic matter and when there is sufficient oxygen, i.e., air, no putrefaction or other odors result. Success depends upon the following treatment:

(1) The garbage must not be buried so deep that bacteria activity is reduced.

(2) The garbage must not be spread in a thick layer on the surface of the ground.

(3) The ground must be sufficiently open and drained so that air can penetrate to a sufficient depth.

(4) The garbage must not overload the soil, but must be sufficiently diluted with earth, ashes and rubbish, so that putrefaction may take place, due to the presence of an ample supply of air in the pores of the soil.

This method has been demonstrated to be not only sanitary, free from nuisance when properly carried out, but economical as well. The Health Commissioner of Seattle describes their system and results as follows:

"This method of filling works very satisfactorily in this climate, but I believe it necessary to include all waste materials, as ashes, boxes, tin cans, etc. These all assist oxygenation and nitrification. I do not believe pure garbage can be handled in this way.

"We also find that it is best to keep as little of the face of the fill exposed as possible. It is always best to keep a man constantly on the job, whose duty is to rake down to the bottom of the fill all boxes, rough materials, etc., thus leaving the ashes to form a covering on top. When this is not sufficient, we cover with a layer of earth about five inches thick.

"The success lies in the proper mixture of waste materials, and next the fill must be properly covered to protect from flies. Chemicals can also be used to protect same. This covering also prevents the slight sour odor of fresh garbage and by keeping out the sunlight, at the same time encourages bacterial growth by increasing the warmth inside of the fill. People residing within one hundred feet of these fills make no complaint, but the public has to be educated when you first adopt this method. We aim to fill city property, as ravines, swampy lands or docks on the lake or salt water front.

"Our laboratory findings show that the process is simply one of slow incineration by nature, instead of the expensive method of burning by incinerators, and at the same time help prove that there is nothing detrimental to public health in these fills.

"We have eleven fills distributed over our city, thus making short hauls, and these are taken care of by eleven laborers, disposing of approximately three hundred and fifty tons per day by this method alone, while one incinerator with about an equal pay-roll will only dispose of sixty to seventy-five tons per day, running twenty-four hours. A fill increases the value of property, while the refuse from our incinerator has to be hauled away at an added cost."

The Health Commissioner in 1913 reported that after spreading, there was applied an antiseptic spray of crude carbolic acid, rosin and caustic soda to kill eggs and larvia of flies, mosquitoes and other insects that might breed.

Burial

Garbage may be buried either by putting it in shallow trenches and covering with the excavation from the trenches for the next day's deposit, or by ploughing under. It digests and is thoroughly taken up or oxidized by the action of the soil.

A summary of the opinions indicates that disposal by burying when properly conducted and when the point of disposal is suitably located gives no cause for objection from a sanitary standpoint. The principal objections are the extremely long haul, the amount of land necessary and no direct income. In small communities this method is entirely satisfactory. It is usually not applicable to large communities.

Disposal Plants

There are two methods of disposing of garbage in plants; incineration and destruction. There is a wide diversity of opinion among experts and city officials as to which is the better from a sanitary and financial standpoint. There is, however, nearly universal opinion upon the following:

1. That the revenue from the by-products of municipally owned and operated plants will not pay the combined cost of collection and disposal.

2. That with only a few exceptions, the revenue from the by-products of municipally owned plants pays the cost of disposal.

3. That the price received by cities from contractors is, with a very few exceptions, not sufficient to pay the cost of collection.

4. That the disposal of garbage by the reduction process is uneconomical for a city with a population of less than 100,000. Some experts increase the size to 150,000 and one to 200,000.

5. That incineration is better than reduction for a city with a population less than 100,000.

In the report of the Chicago Waste Commission, some general rules are laid down for the design of a disposal works, irrespective of method. It says that the design should permit the plant to be operated as a whole, or in part, so that each part can be operated as an independent unit. This will permit one or more parts to receive attention and be repaired during the season when the minimum quantity of refuse is to be disposed of. The details of the plant should be such as to permit cleanliness at all times and hosing and washing so as not to permit garbage dust or dirt to accumulate, flies to breed and material to decompose. All material, so far as possible, should be enclosed during the process of disposal and the odors eliminated or confined and deoderized. The handling of material in the plants, so far as possible, should be eliminated, where mechanical means can economically be adopted. Special attention should be paid to ventilation and the elimination of dust where men are required to work.

The odors or nuisances caused from disposal plants will usually arise from one or more of the following sources: Garbage or refuse, incomplete combustion or combustion temperatures not sufficient to eliminate odors, congestion of carts in one locality and creation of dust. The odors arising from raw garbage which are found in all plants are mostly local and will not create a nuisance a short distance from the point of handling and the housing of equipment used in hauling.

Incineration

Two kinds of plants are used for this method of disposal,—crematories and destructors. Many destructors are in operation in America, but of the crematories which have been built, many have been abandoned. Heat for destruction must be obtained not only from the garbage itself, but also from ashes and other combustible waste. It is here that the difference between destructors and crematories enters. In the former, heat is obtained from the refuse itself; in the latter, garbage is burned at the expense of coal, wood or oil. It seems to be the prevailing opinion that in order to make incineration a success the material must be burned at a high temperature and rapid rate of combustion.

Morse claims that destructors require twenty per cent. less area of ground, cost fifteen per cent. more for boiler and machinery; that the construction is more durable; no addition of fuel; that the gases of combustion are consumed, and that this method has by-products of clinker and power and destroys all combustible refuse, and that the net cost of operation is less per ton.

Crematories, he says, require more ground and more time for disposal, but cost less. They are less durable, require addition of fuel, gases are incompletely destroyed, cannot develop power, the residue has no value and they can burn only garbage and rubbish. The gross cost of operation is a trifle less, but the net cost is more.

Tests of garbage crematories in Ohio, according to the State Board of Health, show that "the plants as operated fail usually to dispose of the garbage at a temperature high enough to avoid the production of odors." This, says J. T. Featherston, is significant and conclusive.

Regarding mixed refuse destruction, Featherston says: "Three features may be noted: No added fuel is required, steam power is produced and quite a residue (clinker) results. Compared with tests of garbage crematories the average destructor temperatures in connection with the gas analyses indicate freedom from odor due to unconsumed gas. Thus the mixed refuse type of plant corrects the inherent defects of the garbage crematory."

Cost of Incineration

The cost of incineration plants depends upon the garbage to be handled. The various incinerator companies usually estimate the capacity of the plant at about one ton per 1,000 population.

Reports show that disposal by incineration in Ohio is confined to cities of from 20,000 to 80,000 population, and that its success has been confined to the very large and to the rather small cities of the country. Some assert that it is applicable in the very large cities only when the collection systems are suitable to provide for the burning of mixed refuse. In small cities it is the custom to cremate the garbage alone, the other classes of waste being dumped or buried.

The cost of construction, reports show, ranges from $600 to $1,000 per ton capacity. The Worcester Special Waste Commission says that "from a calculation based on some thirty incinerators it has been found that the cost per ton daily capacity varies from $250 to $1,000, the average being between $600 and $700."

The by-products are clinker and the steam generated.

Robert W. Wylde says that the cost of operating destructors "is in a great measure offset and frequently quite overbalanced by the revenue" from the sale of steam and clinker. One hundred tons of refuse burned during 16 hours a day produces 800 engine h.p. Clinker from 100 tons might amount to 30 tons per day and would bring $1.00 a ton in many localities. Another expert says that one pound of refuse has been found to produce ½ to 1¾ pounds of steam. The value of refuse as a fuel is estimated by one expert to be 40 cents per ton.

The Chicago Waste Commission report points out, "that experience in connection with the development of power from refuse furnaces demonstrates that it is not easy to find an available use whereby the power developed can be utilized regularly as produced and the furnace operated continuously. In the majority of plants constructed, it has not been possible to utilize all the power available, and in most cases the use is limited to the operation of the plant. When power developed is used in lighting and power stations, the demand only comes during a part of the day. Supplementary coal-fired boilers are usually found in connection with destructor-electric lighting stations, or else the destructor is much larger than would be required to deal with the refuse alone. The power produced from refuse furnaces will best be utilized by some local industry, such as ice-making plants or electro-chemical plants, which require continuous operation. When power is used in connection with pumping plants, it is found good practice to operate the refuse plant only as an auxiliary to the power plant of the pumping station. The saving that results or credit that can be given the destructor plant will amount to the value of the fuel equal to that which it requires to produce the amount of steam developed and used. The fluctuating amount of power developed in most cases can be depended upon only for the average minimum production. In selecting a site for the location of a refuse disposal plant from which power is developed it is not always profitable to utilize the power where the demand is not constant and where the demand would be constant, suitable sites are not always available."

Venable says that if a city has a steam power plant, it will pay, but it will not pay to build one for that purpose.

In a suburb of Montreal, the refuse destructor is constructed in connection with a municipal electric light power station and power is used in generating electricity for lighting purposes. The plant is operated only during the time when lighting load is in demand, and the material as delivered is stored during the day and burned at night. Only a part of the power is furnished by the refuse furnaces, the remainder being obtained from a coal-fired boiler plant.

In Savannah, Ga., the waterworks boilers are kept in service, with banked fires, to use in case of shortage of garbage.

(Concluded in next Issue)

Personal

Mr. George Herrick Duggan, recently elected president of the Canadian Society of Civil Engineers, has had a wide experience as an engineer. He is a native of Toronto, born in 1862. He was educated at Upper Canada College, and at the School of Practical Science,

Courtesy International Press

Mr. G. H. Duggan.

University of Toronto, taking a post graduate course in 1884-86. Mr. Duggan joined the engineering department of the C. P. R. in 1886. From 1891 to 1901 he was chief engineer of the Dominion Bridge Company. Later he was appointed assistant to the president and consulting engineer of the Dominion Steel Company and Dominion Coal Company, and from 1904 to 1910 was second vice-president and general manager of the latter company. In 1910 Mr. Duggan was appointed vice-president and general manager of the Dominion Bridge Company, a position he still holds. He is also chief engineer of the St. Lawrence Bridge Company, the contractors for the steel work of the Quebec bridge; vice-president of the Montreal Ammunition Company; and director of the Montreal Trust Company. He joined the Canadian Society of Civil Engineers in 1888, became a member in 1890, and was for ten years a member of the Council. In 1906 he was vice-president of the Canadian Mining Institution, being on the Council of the same society during 1911-13. He is also a member of the Institution of Civil Engineers, England, and of the American Society of Civil Engineers.

Mr. Duggan takes a great interest in sport, particularly in yachting, and is a member of several yacht clubs; he has designed and sailed winning yachts in the Seawanhaka International Cup races. In 1893 Mr. Duggan was awarded the Royal Humane Society's bronze medal and certificate. In October last Mr. Duggan lost one of his two sons, H. S. Duggan, R. E., who was killed in action.

Colonel Stewart, of the 86th Machine Gun Battalion, now on active service, is the senior member of Stewart & Witton, the well-known architects of the city of Hamilton.

George T. Evans, architect, Hamilton, has received a commission in the C. A. S. C., and will go to Quebec shortly to qualify.

New Monitor Transit

The C. L. Berger & Sons, manufacturers of surveying, engineering, and astronomical instruments, 37 Williams Street, Boston, have developed a new type of transit and level known as the "Monitor," which is claimed to be a distinct improvement both in design and construction of field instruments. These new instruments include several new features, the most striking of which are the exceptionally rugged, strong, and rigid standards. The manufacturers also claim the following characteristic features for these instruments: outer forms rounded, of greater stiffness, and water-shedding; tripod heads of rigid construction; centres long and stout; non-cramping levelling head; unyielding and quick-acting clamps; improved vernier arrangement; water-tight compass box; simplified combination of needle lifter with arrangement for instantaneously setting against declination east or west; telescope standards and vernier plates of great lateral stability; eye piece cap of large diameter; arrangement of centering instrument from point above; levelling instruments set low on tripod; protection to spirit level and slides; and so on.

Montreal Wages Schedule

At a joint meeting of the Builders' Exchange and the Building Trades' Council held in Montreal recently the following schedule of rates was suggested to the Board of Control for the year 1916: Stone masons, 40c.; bricklayers, 45c.; structural iron workers, 30c.; ornamental iron workers, 27½c.; plasterers, 40c.; lathers—metal, 40c.; lathers—wood, 35c.; hoisting engineers, 35c.; tile setters, 45c.; plumbers, 40c.; steam fitters, 40c.; steam fitters' helpers, 25c.; carpenters, 35c.; stone cutters, 45c.; marble cutters, 40c.; marble setters, 40c.; painters, 30c.; sheet metal workers, 35c.; roofers, 35c.; electrical workers, 35c.; cement finishers, 40c.; elevator constructors, 35c.; laborers—common, 20c.; laborers—hod carriers, 22½c.

Steel Bridge over Sauvage River, P. Q.

The general contract for the construction of a bridge over the Sauvage River at Lambton, County Frontenac, P. Q., has been let to Messrs. Galbraith & Cate, Limited, Montreal, the steel being supplied by the Dominion Bridge Company. Tenders sent in were for a wooden bridge and a steel bridge, and the Quebec Streams Commission, for whom the work will be done, decided on a steel structure, which will replace the present one. The new bridge will have three spans of 180 feet each, supported on two concrete piers and two abutments resting on solid rock. The piers will be 52 feet high from rock bottom, or 31 feet above low water. The bridge will contain 200 tons of steel, Warren truss spans being adopted, designed to specifications of the Public Works Department. The contract price of the work is $46,734. Mr. O. Lefebvre is the chief engineer of the Commission.

In order to take care of its rapidly increasing business, the Osgood Company, of Marion, Ohio, manufacturers of steam shovels and dredges, has found it necessary to double its capacity and has purchased the manufacturing plant of the Ohio Tractor Company. The larger machine tools, for which crane service is desirable, will be moved to the main plant of the Osgood Company, while the smaller tools and the foundry will be operated at their present location. The Ohio Tractor Company has acquired a new site in the south part of Marion, and is making arrangements to increase its output.

Only one company, the National Brick Company, of Laprairie, Limited, tendered for the supply of three million bricks required by the city of Montreal. The price was $8.25 per 1,000 f.o.b. cars or $9.50 delivered on the job. The Controllers accepted the latter bid.

The London Concrete Machinery Company have secured the contract to furnish the Chatham Cement Tile Company with one 10 cu. ft. batch mixer to be used in their tile plant at Chatham.

New Books

Elevators—by John H. Jallings; American Technical Society, Chicago, publishers. This is a practical treatise on the development and design of hand, belt, steam, hydraulic and electric elevators, written by an author who has had nearly fifty years of actual experience in elevator building and who has been a witness of all the wonderful changes that have taken place during this time, as well as a contributor to the development of many of them. The book is divided into three sections; part one deals with hand-power elevators, belt-power elevators and worm and gear; part two deals with steam elevators, and hydraulic elevators; part three, motor elevators. As the available literature on elevator construction and design is very meagre it is believed that this volume will find a popular place in the elevator field and satisfy a real demand. 217 pages; well illustrated; size 8½ x 5½; bound in red cloth.

Building Blocks—booklet issued by the Cast Stone Block and Machine Company, Limited, Windsor, Ont., describing the cast stone system of manufacturing granite veneered cement building blocks. The booklet is well illustrated throughout with various types of block and machinery manufactured by this company.

Mainly Constructional

The London Concrete Machinery Company, of London, Ont., have secured the contract to furnish six ½-yard batch mixers to be shipped to Les Fils de Jules Weitz, of Lyons, France.

The Doty Engine Company, Limited, of Toronto, has been incorporated with a capitalization of $100,000. The company will carry on a general mechanical engineering business.

The value of the building permits issued by the city of London in February was $18,765, as compared with $13,500 for the same month of 1915. The total for January and February was $37,995—nearly $13,000 more than for the same period of 1915.

Lieut. George T. Evans, architect, Hamilton, Ont., has gone to Quebec to qualify for his commission in the Army Service Corps. Lieut. Evans is a graduate of the University of Pennsylvania, and a member of the Ontario Association of Architects. He has been practising his profession for about two years.

What is said to be the first highway for the exclusive use of automobiles ever built was finished recently between Tampico and Panuco, Mexico, a distance of about thirty-five miles. The highway was constructed by the oil companies, and is for the use of motor trucks and automobiles in extensive oil operations at Panuco.

It is announced that the National Construction Company, Limited, the contractors for the new Law Courts Building at Winnipeg, have made an assignment, and are found to have a deficit of approximately $101,000. A committee of creditors, assisted by Mr. C. H. Newton, official assignee, are investigating the company's affairs.

A Winnipeg company has been formed to open a granite quarry in the district east of Winnipeg traversed by the Greater Winnipeg Water District Railway. Former Controller McArthur and A. L. McIntyre, a stone worker, are interested in the enterprise. It is said that the granite in the deposit is equal to that now being imported from Eastern Canada.

Former members of the city of Vancouver's engineering staff who have joined the Empire's military forces since the war began are: Private B. E. Spencer, 1st Australian Brigade; Lieut. P. O. Spicer, Royal Engineers; Sergt. W. W. Sayer, Canadian Engineers (died at Comox); Private W. L. Railton, 67th Battalion; Private H. Whillier, 72nd Highlanders, and Private M. Stanbridge, 72nd Highlanders.

Members of the Legislature paid a visit to the limestone quarries and stone-cutting plant of the Wallace Sandstone Quarries, Limited, near Tyndall, on February 24. From these quarries comes the well-known Tyndall stone, which is being used in the construction of the new Parliament Buildings, Winnipeg. The party, which was composed of thirty members of the legislature, several Winnipeg architects, and two professors of the University, were conducted over the plant by Messrs. Peter Lyall and A. U. Cote, respectively director and manager of the Wallace Sandstone Quarries, Limited.

The city of Quebec issued thirty-six building permits, of a value of $57,020, during the month of February. This is an increase over the same month of last year of $2,722. There is a large increase for the first two months of 1916 over the corresponding period of 1915. Last year from January 1st to March 1st there were 79 permits issued for the sum of $82,203, while from January 1st to March 1st of the present year 62 permits have been given out to the sum of $118,565. While the number of permits are fewer this year so far, the value of the work being done is considerably in excess of that of last year.

A detailed description of the Government's great floating drydock at Prince Rupert was given on March 2 by Mr Pillsbury, of the engineering staff of the Grand Trunk Railway, and engineer in charge of the construction of the northern dock, before the members of the Vancouver Branch of the Canadian Society of Civil Engineers. The dock has a lifting capacity of 20,000 tons—about the tonnage of a steamer of 650 feet. It is in three sections, each one capable of being sunk and lifted independently for the accommodation of smaller vessels. In connection with it there is a very complete plant, including light and power plant, machine shop, and shipbuilding plant. The cost of the whole plant, dock and all, had been $2,600,000, but the cost of the dock and its accessories was about $800,000.

An interesting departure from the ordinary methods of home-building is being introduced into Quebec by Mr. V. R. Lamontagne, real estate broker and architectural builder. Mr. Lamontagne has bought outright, at a low figure, a block of city land, which he has divided into lots forty feet wide. Special arrangements have been made with regard to building material whereby a substantial reduction in price can be offered. In order to facilitate the building up of this district, Mr. Lamontagne is prepared to asist his clients in every possible way, and to this end has secured the services of an experienced architectural designer and construction expert. Artistic appearance is to be combined with economical construction, and the purchaser of a lot and house has at his disposal the best advice as to design and arrangement of his home, and obtains all the most modern conveniences, every need being supplied from one source at moderate prices.

The municipal officials of Ladner, B. C., are considering the advisability of inaugurating a new style of road construction in the Delta. Recently a representative of the Columbia Bitulithic Paving Company, of Vancouver, made a proposition to the council for the laying of a blanket paving on a mile of road as an experiment. The roadway which it is proposed to treat with this material, if a decision is arrived at, is the main highway for one mile from Garvey Road to Benson Road. Some of the councillors are of the opinion that under present conditions the expense would be too heavy.

The efforts of the Toronto-Hamilton Highway Commission to secure a number of special privileges for the new inter-city highway, as embodied in their bill which will be presented to the Legislature at this session, are not acceptable to the members of the York County Council. At a meeting of the Legislative Committee, held on March 3, in the County Municipal offices, Toronto, the members, after a lengthy discussion, decided to strenuously oppose the granting of any special legislation to the Toronto-Hamilton Commission.

The Montreal papers state that the city of Montreal is saddled with three million brick that they do not want. A requisition for bricks came in from the Sewer Department, on the representation that there were none on hand. The Board of Control called for tenders, and on March 3 last gave an order for three million brick to the National Brick Company. Later it was discovered that there was an uncompleted order for two million brick, of which a million were available for immediate delivery. To complicate matters further, at a meeting of the Board of Control held on March 6, Controller Giroux presented a letter from the L'Islet Brick Company, which declared that company's willingness to furnish the city with brick at lower prices than any other firm was charging. The letter was dated February 26, and stamped "received" that date. Mr. Giroux wanted to know why it had been held back until the brick contract has been awarded. The Mayor demanded an investigation. Failing to find the culprit, the Board took the next move, and asked the Law Department to see if there was any way of cancelling the big contract, or of reducing it.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Aylmer, Que.
The Town Council have been ordered by the Provincial Board of Health to construct a filtration plant. Estimated cost, $20,000. Clerk, A. Malherbe.

Bienville, Que.
The Municipality have had plans prepared for the construction of water and drainage systems on Wolfe Street, estimated to cost $4,000. Engineer. C. Lessard, City Engineer, Levis.

Hull, Que.
The City Council have been instructed by the Provincial Board of Health to instal a mechanical filtration plant, estimated to cost $200,000. Engineer, J. P. A. Laforest.

Lethbridge, Alta.
Work will start shortly on the construction of a sewer to connect the Duff addition sewers with the disposal plant. Estimated cost, $7,500. Engineer, W. S. Harvey.

London, Ont.
The City Council propose to spend $4,000 on the construction of sanitary and storm sewers on Grand Avenue, and also to lay a sanitary sewer on Inkerman Street. Engineer, H. A. Brazier.

Orillia, Ont.
The Town Council are considering the installation of new machinery at the sewage pumping station. Engineer, W. K. Greenwood.

Rougemont Village, Que.
The Municipal Council intend to construct cement sidewalks, estimated to cost $8,000. Secretary, A. Ledoux.

CONTRACTS AWARDED

Elmira, Ont.

Pointe Aux Trembles, Que.

The Imperial Oil Company have let a contract for the supply of about 3,000,000 brick to the National Brick Company of Laprairie, Victoria Square, Montreal.

Subsurface Land Slip Causes Building Collapse at Baltimore

A subsurface earth movement in connection with nearby dredging brought about the settlement of a large area of ground and the collapse of a stock shed of the American Agricultural Chemical Company in the Canton pier district, Baltimore. Dredging was in progress at the time in preparation for the erection of a new coal pier for the Pennsylvania Railroad.

The stock shed faces on Clinton Street, and runs back about 300 ft. to a bulkhead near the pier head line of the harbor. It is one of a group of light timber sheds, consisting of a series of open bays with about 30 ft. between rows of timber columns, which rest on concrete pedestals. The shed floor is paved with a bituminous concrete.

The level of the shed floor was about 11 ft. above mean tide. On the side where the settlement occurred, there was originally a plot of open land, several hundred feet wide, and extending from the bulkhead to the street; that is, covering the inshore end of the new coal pier site. The specifications required that the site be excavated to a 35-ft. depth in the slip at the side of the pier, it being planned to leave the excavated bank on a slope of about 1½ to 1 without bulkheading, since adjacent cuts in the local strata of sandy clay, hard sand and iron stood almost vertically, and other slopes within 500 ft. had stood up for years. The shoulder of the slope was fixed about 15 ft. outside the line of the chemical stock shed, which brought its toe about 75 ft. away.

The dredges had been working in the pier slip prior to the settlement, principallly beyond the toe of the slope, but, shortly beforehand, one of them had been trimming the slope at a depth of aout 16 feet. About three or four weeks before the collapse of the building a crack was noticed in the floor of the shed. No special significance was attached to this, since it was from 30 to 60 ft. back from the shoulder line of the dredging and nearly 300 ft. from the harbor bulkhead. The crack widened somewhat as the work progressed, and some settlement occurred. Several shed columns were shimmed up, but it was taken to e only a small local settlement which could be adjusted after the dredging was completed.

On February 2 an area of the shed flood, 60 ft. wide by about 200 ft. long, dropped to a maximum depth of 8 ft., taking the building with it. The greater depth was on a sheer perpendicular cleavage along the line most remote from the water. The slope was thence upward to the original ground level near the outer line of the shed. A tonnage of land at original level, tapering from 15 ft. wide at its inshore end to nothing at its outshore end, remained undisturbed between the sunken area and the pier site, leaving the shoulder of the excavation practically intact for a distance of about 50 ft. from the harbor bulkhead, where it had also sunk under water. The sunken area was then landlocked for a distance of 150 ft. There was apparently a movement from beneath the area of the shed diagonally out toward the harbor. It is thought this was due to the gradual bleeding of a large pocket of sand, though most of the material taken out by the dredges had been noted to be clayey, with no undue amount of loose sand.

The situation will be met by driving sheet piling along the inland line of the break to check any further tendency toward movement, then bulkheading the slip after dredging, and finally filling back of the bulkhead.

Tenders Without Competition

THE town of Drummondville, P. Q., is asking for tenders on a gravity filtration plant. This in itself would scarcely call for editorial comment if the method of procedure were along usual lines, but the fact is that tenders are being called —competitive tenders—on specifications prepared by a firm of consulting engineers, that are worded so deliberately that competition in certain parts of the work is entirely eliminated. So much so that these specifications definitely state the manufacturer from whom the various equipments must be purchased—the pumps must be so-and-so's make, the gas engine so-and-so, the motors so-and-so. This holds throughout the entire list. They even go so far as to give the name of the sub-contractor who must supply and install certain of the equipment. Indeed, the only thing that seems to have been omitted in these specifications is the name of the general contractor who will be awarded the contract for which so-called tenders are now being asked —doubtless merely an oversight.

It is scarcely possible, we believe, to condemn in too strong terms such a pernicious and unbusinesslike way of conducting municipal matters. It must be condemned on four counts at least. (1) there is no assurance that the most suitable equipment for the purpose, considering operating conditions, manufacturers' guarantees, price, etc., is being installed; (2) there is a possibility, to put it mildly, that the price paid for this equipment, purchased under compulsion, a fact known to the manufacturer, will be unduly high; (3) there is the unfairness to competitors of good standing in the field who have earned the right to be heard; and (4) there is the almost certain result of doing public business in other than an entirely open and aboveboard way—that there will be charges and suspicions of graft.

* * *

To the first it may perhaps be answered that the best in each case has been selected. With all due consideration for the names mentioned in this particular case, we do not think this argument can reasonably be advanced in the present highly developed state of our commercial life. To-day it is not a matter of choosing the best, but rather a question of choosing from among the best. And this condition, it is only fair to recognize, has been brought about, more than through any other agency, by competition. As a matter of recognized fact, the conditions surrounding counts 1 and 2, that is, both high quality and reasonable price, are directly due to the very principle of competition that this municipality is so deliberately ignoring.

For this reason too, if for no other, competitors have a just right to be heard in favor of the particular equipment they manufacture and sell. Manufacturers and salesmen must to-day be recognized as specialists, each in his own particular line. The history of the past few years has taught us that merit more often than not is democratic, and may be found as intimately associated with some of our younger industries as with those of time honored names. But this can, in general, only be learned through investigation and demonstration and it is for this purpose chiefly that salesman specialists are employed—to demonstrate the merits of their goods. It follows then that these men must be heard before the merits of their goods can be properly appreciated.

On the fourth count, public opinion, there is perhaps little that can be said that is not mere repetition. Honest men and crooks look alike from the outside and apparently about the only way the public have of defending themselves from dishonest officialdom is to suspect everybody. The onus of proof thus rests with the officials and in consequence the wiser course is surely to so conduct public business that the light of day has free access to every item. The people pay the bills. Is it not their right to know how and why the money is spent?

* * *

The only reasonable course for Drummondville, or any other municipality, to pursue in such a case is to get away, as far as possible, from this idea of doing things in an arbitrary way. To-day we are fighting for freedom, at home and abroad—freedom of thought, freedom of action, freedom from dictation by any individual or group of individuals who would force their opinions upon us. It is the basis of our national strength—the right of men to be heard—the right of every individual to be given a chance to convert others to his way of thinking. The Drummondville council will be well advised to reconsider their present course and to start all over again, call for tenders for equipment in the usual way and give everybody a fair chance. The rights of the citizens of Drummondville demand this, and, no less, the rights of those men whose competition is responsible for the present favorable conditions of quality and price surrounding, in general, machinery equipment on the Canadian market.

Disposal of Garbage

DIFFERENT systems of collecting and disposing of garbage, and the factors which affect their cost, form the basis of an extensive investigation and a subsequent report just to hand by the State Bureau of Municipal Information in the New York State conference of mayors and city officials. This report, extracts from which appear in this issue, has been prepared as a guide for cities desiring either to establish garbage systems or improve existing ones.

The garbage problem falls naturally into two divisions—collection and disposal. Treating these separately, collection may be either combined or separate, or some combination of the two—for instance, separate collection of garbage and combined collection of ashes and rubbish. Reports agree that if all wastes are collected together the cost of collection will be less than if collected separately. The method of collection may be either by licensed cartmen, those served paying the expense; by contract, where the city pays a fixed sum annually to some contractor; or by the municipal system, where the city does the work. Experts are agreed that the last named system is the best. Service is rendered as desired, the system is under better control, is carried on with better equipment and is generally much cheaper to the tax-payer.

The kind of equipment, location of receptacles, and frequency of collection are big factors which vitally affect the cost of collection. Most cities specify the size of can, and where it must be left for collection. No standard type of wagon has so far been adopted in the U. S. cities, different cities employing different designs such as suit their ideas and requirements. The almost universal practice is to collect during the day. The frequency of collection depends entirely upon the amount of garbage, the density and character of the population, and the season of the year. The cost of collection is vitally affected by so many different factors that any attempt to compare the economy of a system in one city with that in another would generally be unsatisfactory. The cost of collection depends on the cost of loading, length of haul, capacity of wagon, rate of travel, grades, and traffic obstruction.

The methods adopted by different cities for the disposal of their garbage are: feeding to swine; dumping on land; dumping into large volumes of water; disposal by sanitary fill; burial; incineration; and reduction. Most of the smaller cities dispose of all or part of their garbage by feeding to swine The method is a most profitable one, and warrants consideration in small cities where isolated farm sites are available. Dumping on land, especially where there is a large quantity to be disposed of, is objectionable. Dumping in water is generally prohibited because the material is washed on a neighboring shore. The method of sanitary fill, in dumping the garbage and mixing with it sufficient earth to ensure oxidation, is not only satisfactory, and free from nuisance when properly carried out, but economical as well in filling excavations and ravines. Disposal by burial, when properly conducted, is sanitary, but is not applicable for large communities, on account of the large area of land required.

The system generally employed by large cities is a disposal plant, either by incineration or reduction. Incineration is favored for a city of less than one hundred thousand inhabitants. From estimates it has been found that the average cost of incineration is between $600 and $700 per ton daily capacity. The by-products of this process are clinker, used in brick manufacture and road-making, and heat that can be used for steam generation of light and power.

In the reduction method of disposal two processes are used—cooking and drying. In the former the garbage is cooked in large closed retorts by means of steam under pressure. In the drying process the grease is extracted by some volatile solvent like naptha. Reduction is a method that to be financially profitable can only be adopted in large cities. The cost of reduction will vary from $1,500 to $3,000 per ton daily capacity. Besides being sanitary, the reduction process is profitable in the intrinsic value of the components restored—grease, tankage, hides, etc.

The report is specially complete and valuable with regard to disposal by incineration and reduction. Liberal extracts from the data furnished under the headings are printed elsewhere in our issue of March 15 and of the present date.

The Recent Road Congress

The proceedings of the third Canadian and International Roads Congress, held in Montreal, were indicative of a strong interest in the good roads movement, partly due to the spirit created by the first Congress, also held in Montreal two years ago, but also very largely to the Good Roads legislation of the Provincial Governments. These governments gave the Congress very strenuous support; several members attended, and some of the speakers were officials in the highways departments. The efforts of the Gouin Ministry have clearly had very beneficial results in awakening interest in the improvement of roads, as was evidenced by the large number of delegates from that province. This was scarcely less noticeable in the case of Ontario and also Manitoba. The executive of the Congress met the desires of the section of the community in which the Congress was held by arranging for several papers to be read in French and by prominent French Canadians presiding at some of the sessions.

As compared with the First Congress, there was a marked all round improvement. The proceedings were more enthusiastic, the exhibition more attractive, and there was a general atmosphere of quickened vitality. The Congress was of real educational value, and will undoubtedly further stimulate the Good Roads movement. Rural municipalities are very hard to move, often looking upon such subjects as good roads in the light of unnecessary expenditure; the feeling expressed in the saying that what was good enough for their fathers is good enough now is still widely held by many men in farming districts, and it is difficult to upset deep rooted prejudices of this character. Such congresses as that held in Montreal are worthy of support, if only from the point of showing that good roads are profitable investments for the farmer, and the delegates who go back to their towns and villages impressed with this knowledge will help to remove one of the chief obstacles to the advance of the movement. Show the farmer that he is spending money to his financial advantage, and you have made a convert.

There were two or three points about the congress in connection with which one heard an occasional criticism. One was that the majority of the papers were too technical. To the engineers such papers are of great value, but the majority of the delegates were not of this class, and it is significant that the most popular speakers were men who mixed their technical data with more general observations. Then, again, several of the papers were criticised as being too long; they were weighted with too much detail, so that interest was apt to be lost by reason of the mass of information read off at a rapid rate. Delegates are apt to become wearied when a paper exceeds a reasonable limit, (except perhaps a few who have made that particular subject a study), especially when they have perhaps sat for an hour and a half listening to other papers. And finally, the discussions were on the whole, disappointing. Most of the papers passed without comment. This may in a degree be partly accounted for by the disinclination of the French Canadians to discuss the papers written in English, and vice versa, but even the papers in French were followed by little comment. The language question was one of difficulty, but it was met as fully as possible by Mr. B. Michaud, the president, alternating his speeches in French and English.

A Conference of Toy Manufacturers

With a view to encouraging the manufacture of toys in Canada, both for home markets and for export, a toy conference has been arranged to take place in the Royal Bank Building, King and Yonge Streets, Toronto, on the 28th of March. A large number of samples of German toys, such as were formerly imported into Canada, will be on exhibition to show Canadian manufacturers what the Germans supplied, and there will be a collection of U. S. toys also, which will indicate what our neighbors to the south have been doing to replace the German article. It is also expected that Canadian manufacturers of toys will send samples. There has been a very considerable development of toy manufacturing in Canada since the outbreak of the war, and it is known that there are not less than twenty-four toy factories in Canada at the present time. The importance of the industry and the wonderful demand at certain times of the year, would indicate the necessity of Canadian manufacturers attending this conference as a preparatory step towards holding this particular trade permanently.

Good Roads in Quebec

The Hon. L. A. Teschereau, Minister of Public Works, has presented a Bill before the Legislative Assembly of Quebec to abolish toll-gates on some sixty-four miles of road around the city of Quebec. The roads are at present owned by the Quebec North Shore Turnpike Roads Company, but the revenue from the toll-gates has not been sufficient to maintain the roads, and the company is practically insolvent. The Bill dissolves the company, and the roads and bridges are to be municipalized and become the property of the municipalities through which they run.

The Lieutenant-Governor-in-Council is empowered to create a commission of three men who will look after the road for ten years, at the end of which time the municipalities themselves will take charge. The money for repairs and construction is to be secured by the municipalities under the provisions of the Good Roads Act,—half the cost of maintenance is to be paid by the municipality, one-quarter by the city of Quebec, and the balance by the province, and the total cost of maintenance is not to exceed $40,000 a year.

Mr. Dunlop Before Ottawa Branch

The Ottawa branch of the Canadian Society of Civil Engineers held their third mid-day luncheon for the season in the Green Room of the Russell House on March 17th at which Mr. E. A. Dunlop, M. L. A., Pembroke, Ont., delivered a brief address. Mr. Dunlop has just returned from a trip to Europe where he visited the Canadian front line trenches. He was, therefore, specially fitted to give an account of the life and condition of our soldiers at the front.

Manitoba Branch C.S.C.E.

At a meeting held on March 3 of the General Section of the Manitoba Branch of the Canadian Society of Civil Engineers, Messrs. W. G. Chace and M. V. Sauer gave an interesting review of the present and proposed hydro-electric development in the Niagara Falls district. The differences in the various plants were pointed out, special features were discussed, and the advances made in electric power transmission within the last twenty years were dealt with.

The following list of members of the Manitoba Branch of the Canadian Society of Civil Engineers have enlisted for active military service:—

Lieut. Louis Annereau, A.M.; T. W. Clark, A.M.; W. S. Collins, S.; Major F. A. Creighton, M.; W. J. Dickson, S.; C. O. Donnelly, M.; Lieut. E. P. Fetherstonhaugh, A.M.; J. A. Hesketh, M.; Lieut. B. A. Johnston, S.; C. N. Mitchell, S.; Lieut. J. M. L. G. Mullon, A.M.; R. H. Mulock, A.M.; W. H. Richardson, S.; C. A. Millican, A.M.; L. M. H. Rime, A.M.; Major D. A. Ross, M.; C. Rowan, S.; Col. H. N. Ruttan, M.; G. L. Shanks, J.; W. H. Shillinglaw, M.; V. H. Tait, S.; Lieut. A. J. Taunton.

Monthly Meeting, Toronto Branch C.S.C.E.

The regular monthly meeting of the Toronto Branch of the Canadian Society of Civil Engineers was held in the Society's rooms at the Engineers' Club, 90 King Street West, on Thursday, March 9th. The meeting was devoted to the discussion of proposed amendments to the present by-laws as formulated by the Committee appointed in 1915 to consider this matter. While the attendance was not what the importance of the subject should warrant, a very interesting discussion took place, and many good suggestions were made. A stenographic report of this discussion will be available in a short time for members wishing to consult it. Mr. G. A. Mountain, of the Ottawa Branch, was present at this meeting, and contributed to the discussion.

Canada's total revenue to February 29, for the eleven months of the fiscal year, is $154,348,809. This is an increase of about $34,000,000 over a year ago.

The Monolithic Type of Brick Pavement

The advantages of this type over cushion construction — Description of methods employed

By Maurice B. Greenough*

THE development and successful application of the monolithic type of construction for brick pavements is a decided step in advance in improved highway construction. It promises the end of building roads by rules of thumb and precedent, and the beginnings of truly economical design and construction.

At the present time, the monolithic type is of two kinds, both representing a breaking away from the practice of constructing brick pavements in two parts, separated by a layer of foreign material, but one more gradual than the other. In one we have no radical change in the relationship of the various elements of the structure. It differs from the sand cushion type only in the addition of cement to the cushion course, producing a part which might more properly be called a cement mortar bedding course. A union is made with the finished surface of the concrete base, but it is only such union as may be obtained by bonding a thin layer of cement mortar to a prepared concrete surface, and to the bottoms of vitrified paving brick. The other, as typified by the newly built roads at Paris, Illinois, is a complete divorce from the old order. It represents the final step in consolidating the wearing surface and the foundation, so that both contribute their united strength to the structure. All semblance of a cushion or special bedding course is done away with, and the vitrified wearing surface is completely bonded to the green concrete base.

Before proceeding to a critical analysis of the results obtained by the two methods of monolithic construction, let us examine in detail the steps involved. First, that type in which the bricks are laid directly on the green concrete foundation, developed originally for country roads, but since applied to city streets. The preparation of the subgrade differs in no respect from that of any improved road. Thorough drainage must be insured and a uniformly compacted subgrade created as the foundation.

When the work begins, concrete of a quaking consistency is deposited from a conveyor on the subgrade between the forms. It is then roughly struck off by means of shovels to a depth about two inches greater than the required depth of foundation. The concrete having been deposited, roughly struck off, and spaded along the side forms in order to allow only mortar to come in contact with them, the foundation is struck off to a true surface and luted by means of a double template, in which has been placed a dry premixture of sand and cement in the proportion of one to four.

The character of the double template is of the utmost importance and may well be called the salient feature of this method of construction. As developed at Paris, Ill., and very successfully used there, it consists of a forward cutting edge, an I-beam, and a rear cutting edge, a channel with the flange placed outward. The I-beam and the channel are spaced from two to three feet apart. The bottom of the rear cutter is about three sixteenths of an inch higher than the lower edge of the forward cutter. With the space between the two filled with dry sand and cement, a forward motion of the template first cuts off the concrete and then fills all irregularities in the surface with the luting mixture.

Sufficient water is used in mixing the concrete so that enough will work to the surface and be absorbed by the luting mixture to insure its thorough hardening.

The surface thus created in the rear of the template is remarkably smooth, entirely free from depressions, and is ready to receive at once the brick surface. No difficulty has been experienced in laying the brick in the usual manner, having them brought in on pallets with the best edge upward, the dropper standing upon the brick just laid. There is sufficient rigidity in the green concrete base even at this stage to resist the formation of any depressions in the surface by workmen moving about upon it. It is well, however, to have boards laid for the men to walk upon.

The brick setting is immediately followed by rolling. A light hand roller weighing from four to five hundred pounds has been found entirely adequate to obtain a remarkably smooth surface, in fact, the surface obtained before rolling is as smooth as many sand cushioned streets after rolling.

Fig. 1.—Brick pavement without curbing.

The chief endeavor of highway engineers is to obtain economy in construction, to build pavements for the minimum cost that will promise the maximum of durability, consistent with all the elements that govern pavement construction such as drainage, traffic, and freedom from excessive maintenance and repair. If we compare the two methods of building monolithic brick pavements on the basis of results already demonstrated, we find that the sand cement mortar type has

*Instructor Highway Engineering, Case School Applied Science, Cleveland, before Ohio Engineering Society.

increased the cost of construction, while that method by which the brick are placed on the green concrete base has decreased the cost of construction.

In the sand cement mortar bed type, the base is prepared in advance and allowed to harden exactly as if the sand cushion type were to be built. The same depth of brick is used and the same concrete edging or curb has been retained that were formerly employed. The increase in cost arises through the introduction of the cement in the cushion material. Any saving in the amount of sand used and in allowing faster dropping of the brick is offset by the cost of the cement and the cost of premixing the cement and sand. The net result is an increased cost per square yard for the construction. The sand cement mortar bed type has had its widest appreciation in city practice. One of the advantages of the Paris type is found in the elimination of the curbing or edging for country roads, so that from the point of view of effecting economy in materials this type has the advantage over the sand cement mortar bed type.

Fig. 3—Bricks removed from pavement.

Any innovations in pavement construction methods are of interest to the engineer particularly, since it is he who forms the connecting link between the contractor and the taxpayer. But the contractor is vitally concerned in these innovations since it is he who must adapt his organization to them in order to meet successfully the requirements of the engineer. The public is interested by reason of the fact that it is they who pay for all pavements constructed and enjoy the use of them. Therefore, in order to satisfy all of these interests, a pavement must be of practical construction in the operations and organization involved, it must meet the requirements of all pavements, that is, ease of traction, ease of cleaning and durable under the wear and tear of traffic, and finally it should be attained at the minimum expenditure of money consistent with good service.

Executives are agreed that the maximum efficiency in operation and organization obtain when the same men continue to exercise the same functions, in other words, specialization of effort. What holds, for example, in productive industry, is equally applicable to the construction of pavements. Effective effort on the part of workmen building a road is obtained when each man becomes thoroughly familiar with the work which he has to perform, and particularly if he has but one kind of work to do.

Again, economy in materials, which decreases the amount of money which must be tied up during the prosecution of a contract, appeals strongly to the contractor. A type of construction which promises to be a credit to the man performing the work and one in which the hazards of unknown and unforeseen circumstances are reduced to a minimum commends itself strongly to the contractor.

Fig. 2—Completed brick pavement, Paris, Ill.

All of these conditions are satisfied by the Paris type of monolithic construction. The entire force engaged in building the pavement is distributed over a distance of less than seventy-five feet along the road, encouraging economy by making possible street supervision of all the work. The same men perform the same operations continually. For instance, certain men are always engaged in roughly striking off the concrete base and spading it about the forms; others are mixing the sand and cement luting course and keeping the template well filled; still others are constantly bringing in brick for the droppers, and so on. Thus the entire operation proceeds at a uniform rate of speed throughout the day. There is no confusion or loss of time by changing duties. Economy in materials is effected by the elimination of the curbing or edging in country road construction. A saving is made in the amount of sand and cement required for the luting course over what would be required for a sand cement mortar bedding course, or even a plain sand cushion.

No time is lost in waiting for a concrete base to harden before brick laying may commence. In other words, there is no call for equipment to be brought on to the work until actual operations of constructing the pavement begin. Of course, the subgrade must be prepared, but except in unusual circumstances that may be going on simultaneously with the construction of the pavement only far enough ahead so that no time will be lost by breakdowns or other unforeseen delays in preparing the subgrade.

In the use of the special template which both strikes off and lutes the concrete foundation is found the critical point in construction. No make-shift template should be employed, it should be substantial and designed particularly for the work to be performed by it. The cost of the template is very small in proportion to the economy effected by its use.

Every engineer hesitates to commit himself to new methods of construction, involving the expenditure of large sums of money without being certain of the ground upon which he stands, in order that his name shall not be lent to any plan which may later result in discredit to his professional judgment. This is a natural and justifiable attitude and it serves as a check on exploitation and over zealous attempts to improve methods which have been in use for many years. Unfortunately, we do not as yet have in highway engineering the criteria for predetermining pavement behavior under the diversified conditions of application which surround them, so that opinions upon the future performance of pavements must be based upon "a priori" reasoning, with past performances of accepted methods in view.

The principal defects of the sand cushion type of brick pavements have been longitudinal cracks and surface depressions, caused by soft spots or shifting in the sand cushion, by imperfect grouting, or combinations of the two effects. The presence of moisture in the sand cushion which may freeze and expand during cold spells may also be a contributing factor in the formation of longitudinal cracks. One thing is certain, that the elimination of the sand cushion eliminates its hazards as well, and defects that develop must be attributed to some other source. So far, no longitudinal cracks have developed in monolithic pavements.

The opinion of engineers has been expressed from time to time that they feared that at the end of five or six years, the bricks would become broken and battered on account of the anvil effect of the base when the surface is subjected to moving loads.

We know that the ability of any structure to withstand the shock of suddenly applied loads depends upon the ability of the material to yield slightly and to store within itself internal energy equal to the amount of the external energy applied to produce the given state of distortion. This storage of internal energy is evidenced by the elastic recovery of the structure to its original position upon removal of the load. We commonly describe this function of a pavement as its resiliency. Just what the resiliency of a four-inch brick surface firmly united to a four-inch concrete base will be, is something to be determined by actual measurement.

A careful study of monolithic pavement leads to the conclusion that they are inherently stronger, and better suited to withstand successive deflections without injury than is that type having the wearing surface and the foundation acting separately, the only connection between the two being dependent upon a layer of sand which may or may not establish a contact.

The taxpayer's interest in improved roads lies not only in having a smooth and comfortable road over which to ride, but also in how much he must pay to secure such a road. His interest in monolithic construction is quickened by the knowledge that a type of construction for brick roads has been developed which promises to be equally and probably more satisfactory than the sand cushion type, and as has been indicated by work thus far performed, it is secured at a cheaper price.

Cost of Applying Mortar with the Cement Gun*

The upstream face of the Elephant Butte dam of the United States Reclamation Service is being waterproofed with portland cement mortar mixed in the proportion of one part cement to two parts sand and applied with a cement gun in a coating about 1 in. thick. Advantage has been taken of rising water in the reservoir to work from rafts specially constructed for the purpose. There are two of these, each 9x13 ft., made of planking on a framework laid on and attached to 16 oil barrels. One raft contains the machine, operator and helpers, small mixing box and a few sacks of cement and sand, while the other is loaded with cement and sand.

The coating is applied in horizontal strips about 10 ft. high and the length of the dam at water level.

Fig. 4—Laying brick, Paris, Ill.

The surface is first cleaned thoroughly with scrapers and wire brushes and is then gone over with a sandblast, using coarse sand, passed through the machine to obtain the necessary pressure. This roughens the surface sufficiently to cause the mortar to adhere to it. The surface is then thoroughly moistened with a hose and the mortar immediately applied. The mortar is put on in four layers, each about ¼ in. in thickness. It was found that a thicker coat than this applied on a vertical wall, without reinforcement, would, on account of its weight, slough off before setting. Each

*From the Reclamation Record.

layer follows the preceding one before it has attained its final set, and so far there is no indication of a parting of the layers. Numerous samples taken from the face showed perfect adhesion to the concrete, it being impossible in every case to break the mortar from the concrete at the line of contact. The cost per square foot for the first 100,000 sq. ft. of this coating is as follows:

Operating and repair work, including cost of air and water	$ 0.015
Staging, cleaning wall, moving, etc.	.006
Cement	.024
Sand, including labor, screening and hauling (sand only 20c per cu. yd.)	.007
Depreciation of gun and equipment	.020
Subtotal	$ 0.072
Overhead	.007
Total cost per square foot	$ 0.079

In using the cement gun the sand must be clean, sharp and not too fine. It must not be bone-dry, or trouble with feeding will occur. The air pressure should be about 30 lb. in the gun and the water pressure over 60 lb. It has been figured at Elephant Butte that 30 ft. of free air at 100 lb. pressure at the point of delivery to the gun and 10 gal. of water are required per minute.

Efficiency in Municipal Engineering

By R. O. Wynne-Roberts

IN the article published in the issue of February 9th the writer dealt with the question of efficiency in municipal engineering in general. Since then I have had the opportunity of studying the financial returns of nearly 60 Ontario waterworks as published in a government report for 1913, which is the latest available.

The returns do not appear to be rigorously standardised because in a number of instances the repayment of loans or debentures is included in the annual working expenditure. It would also appear that these repayments are included in other returns although the fact is not stated. Furthermore the dissection or allocation of the accounts in some of the returns do not conform to the standard and, therefore, must be omitted. These conditions are to be regretted, inasmuch as the data given would be of great value to the authorities in order to compare the results obtained in one place with those in another. Such a comparison, however, is not always reliable unless ample information is available as to the nature of the power employed, cost of fuel, type and condition of the pumps, average height to which water is raised, management and operating organizations, and so on.

A professor addressing the Royal Canadian Institute in Toronto recently, referred to "the mendacity of statistics," and without doubt he was stating a truism, for figures without explanations are often most misleading. For example, the cost of providing water by pumping in Ontario municipalities including all expenditures, excepting the repayment of loans or debentures, ranged from $14.00 to about $138.00 per million gallons. This great difference needs explaining and when the average daily consumption is taken into account it is found that it will give a little light. Where the total cost of pumping was only $14.00 per million gallons pumped, the average daily quantity of water per head was as high as 437 gallons, but where the cost was $138.00 the consumption was only 33 gallons. The ratio of the two consumptions was as 13 is to 1 but the cost of production of water was as 1 is to 10. The cost of water production, however, does not mount up in the proportion of the quantity used and wasted. Labor, repairs, salaries, interest, etc., will remain nearly the same, but fuel or electric energy will cost nearly in the same ratio as the quantity of water supplied. Suppose the working expenses, etc., are analysed on the basis of the population, which is the only other basis available in this case, as no statistics are given as to the number of actual customers supplied. The following table furnishes the main items of the year's operation at the above two places, based upon (a) per million gallons supplied and (b) per capita:

	Gross cost	Fuel or Energy	Salaries or Wages	Interest	Gross Earnings	Gallons per head per day
(a) per million gallons –						
1	$ 14.00	4.26	3.58	2.30	16.80	437
2	138.00	9.00	29.50	62.00	213.00	33
(b) per capita –						
1	$ 2.31	0.684	0.574	0.306	2.69	437
2	1.65	0.1078	0.352	0.744	2.55	33

It will be observed that No. 2 would appear to have a very costly water supply if the cost per million gallons is taken as the standard, but when compared on the basis of cost per capita it is the most satisfactory on almost every score. These two places are relatively small, one has a population of over 2,000 and the other over 4,000.

If the same analytical method is applied to larger towns we get the following results:

	Gross Cost	Fuel or Energy	Salaries or wages	Interest	Gross earnings	Gallons per head per day
(a) per million gallons –						
3	$ 57.00	17.50	11.70	14.10	96.00	57
4	46.00	5.20	6.04	26.60†	57.20†	143
5	62.00	6.80	7.70	30.50	84.00	100
(b) per capita						
3	$ 1.18	0.36	0.32	0.29	1.99	57
4	2.40	0.27	0.314	0.93†	2.99†	143
5	2.28	0.25	0.282	1.448	3.05	100

†Includes repayment of loan.

In these instances again the cost of water per million gallons supplied is inversely proportional to the average daily consumption; whilst if based upon the number of inhabitants the cost was lowest where the consumption was low. There are, however, many local circumstances which would tend to alter the above figures, but in the absence of particulars it was impossible to consider them. In most Canadian towns and cities there are some people who have independent water supplies from wells, etc., the number of which is often proportionately greater in a small town than in a large city. Some towns use large quantities of water for public purposes and the industrial use of water in small towns is frequently greater in small towns than in large ones, when compared on the per capita basis.

The financial returns from Ontario towns were analyzed in several ways so as to ascertain the relative cost in different places. The tables built up in this way are too extensive for publication but they indicate that some authorities could save money and at the same time probably have a more efficient water system.

The average daily consumptions, according to the returns, range in a crescendo scale from 29 to 437 gallons per head. Out of 39 towns who reported the consumption

35 consumed over 40 gallons per head per day
32 consumed over 50 gallons per head per day
31 consumed over 60 gallons per head per day
28 consumed over 70 gallons per head per day
27 consumed over 80 gallons per head per day
23 consumed over 90 gallons per head per day
20 consumed over 100 gallons per head per day
7 consumed over 150 gallons per head per day
5 consumed over 200 gallons per head per day
4 consumed over 250 gallons per head per day

There may be excellent reasons for some of the high consumptions, such as industries requiring large quantities of water which are metered and paid for.

If certain U. S. and European manufacturing towns can prosper on 40 gallons or less per head daily, it is evident that 50 gallons should suffice in Canada. As the daily consumption is allowed to mount up it is palpable that the waterworks plants must be sufficient in capacity not only to cope with the regular requirements but also for fire purposes. If the ordinary flow of water through the pumps, filters, reservoirs and mains is two or three times that which is actually necessary, it is easy to anticipate the conditions obtaining when a large supply is required for fire extinction. The capital necessary to be spent to satisfy all these requirements must be great or an inadequate service is provided. It does not matter which, because the ratepayer must pay either in interest or expenditure and for operation expenses, or as surcharge on fire insurance. But if the waterworks system is in a proper condition the ratepayer has neither excess to pay, because by maintaining the plants in a high state of efficiency they are capable of meeting all contingencies at the minimum of cost.

By allowing the water consumption to mount up not only has the ratepayer to bear the extra cost of pumping and extra interest on plant, but the extra water that is allowed to be used and misused simply adds to another burden, namely that of disposing of the sewage. The quantity of sewage to be dealt with is more or less proportional to the volume of fresh water supplied, but the organic matter in sewage is roughly proportional to the population served. Certain features of sewage treatment plants depend more upon the strength of the sewage rather than upon the volume, but this subject need not be discussed further in this connection.

The ratepayers have always to pay for these services, and the point the writer desires to emphasize is that it pays directly and indirectly to avoid waste of water, energy, fuel, labor, and therefore money. Preventable waste, and efficiency are two elements—like oil and water—they will not blend well, if at all.

Unfortunately the returns are incomplete in several respects, consequently it is not possible to include all of the waterworks in this discussion. It is nevertheless interesting to note that out of 20 towns which gave no data as to the daily average consumption per head, 10 had made a profit on the year's operation and 10 had deficits. Where the daily consumption was under 50 gallons per capita one concern had a deficit, four had surpluses. In the towns where the consumption was under 75 gallons per head there were losses in two and surpluses in 7 of them. Carrying the investigation further it was found that with a daily consumption of 100 gallons and less 3 waterworks were run at a loss and 11 with profit, whilst in those towns where the people required more than 100 gallons per day there were 6 waterworks run at a loss and 14 profitably. It will thus be seen that as the consumption per capita mounted up the undertakings operated at a loss increased in number. Out of 54 towns 19 had suffered losses and 35 made profits.

The capital expenditures on waterworks based upon the reported assets were as follows:

		Capital expenditure per capita	Daily Consumption per capita
Cities over 10,000 inhabitants—			
Maximum	(6)	$ 95.30	120
Minimum	(3)	20.60	57
Average		33.45	113
Cities or towns under 10,000 inhabitants—			
Maximum	(7)	$ 51.00	145
Minimum	(8)	7.55	——

Unfortunately, as already stated, the information given in respect to the annual capital charges is indefinite, but if we eliminate those returns which specifically state that repayments of loans or debentures are included in the cost of production we find that the interest charges ranged from $10.70 to $82.20 per million gallons, that is as 1 is to 7.70, or from $0.13 to $3.60 per capita, that is as 1 is to 28. It is known that certain towns have not installed or maintained adequate and efficient water supplies and the above figures tend to prove it.

The cost of fuel and energy in cities of over 10,000 inhabitants differed considerably but in smaller places the range was much greater, as will be seen below:

Cost of Fuel and Energy per Million Gals.	Consumption per Head per day		Cost of Fuel per cap.	Consumption per head per day
		Cities over 10,000 pop.		
(3) $17.50	57 gals.	Maximum	(6) $0.59	120 gals.
(9) 5.20	,143 gals.	Minimum	(5) 0.25	100 gals.
		Cities under 10,000 pop.		
(10) $50.00	29 gals.	Maximum	(12) $1.04	85 gals.
(11) 3.04	356 gals.	Minimum	(13) 0.116	150 gals.

The cost of fuel and energy varied greatly. Some towns have water power available to operate the pumps and as far as the writer's information extends they have not been included in the analyses. When water power is utilized the cost of energy and fuel is reduced but in the absence of figures as to the ratio of water power to steam, electric, oil or gas power no good purpose can be served by pursuing this study.

Salaries and wages amounted to an average of $10.31 per million gallons in cities of over 10,000 inhabitants. They ranged from $4.24 to $20.00. When distributed over the population they amounted to an average of $0.41 per capita ranging from $0.28 to $0.62. In smaller cities and towns this expenditure ranged from $2.36 to $42.50 per million gallons, or $0.13 to $1.19 per capita.

In conclusion it must be clearly understood that the data obtained from the published government report may be subject to considerable revision when the balance sheets for 1915 are analysed. Furthermore the figures quoted herein are used to illustrate the possibilities for reductions in cost of operating waterworks, especially in smaller towns. The ratepayers are ordinarily favorable to the municipalising of public utilities, on the supposition that the services are rendered at cost price and evidently they are. But in many places it is also evident that some of the waterworks would be operated by companies in a different manner and at less cost to the consumers.

The writer has during his professional career consistently advocated the municipal ownership of public utilities, but according to some of the returns there are occasions when the public would receive better service at a lesser cost. In view of the present financial situation when thrift, economy and efficiency count as they have seldom done before, it is important that the exhortations of the governments should be respected even in the management of public utilities. But apart from the need for public frugality it is the natural attitude of customers to strive and get their supplies of commodities at the most economical terms. Water is an absolute necessity; public health, private amenity and general requirements are such that its supply should be pure, abundant and cheap, but such conditions are difficult to maintain without efficiency in the several departments of water undertakings.

Shot Tower for Canada Metal Co.

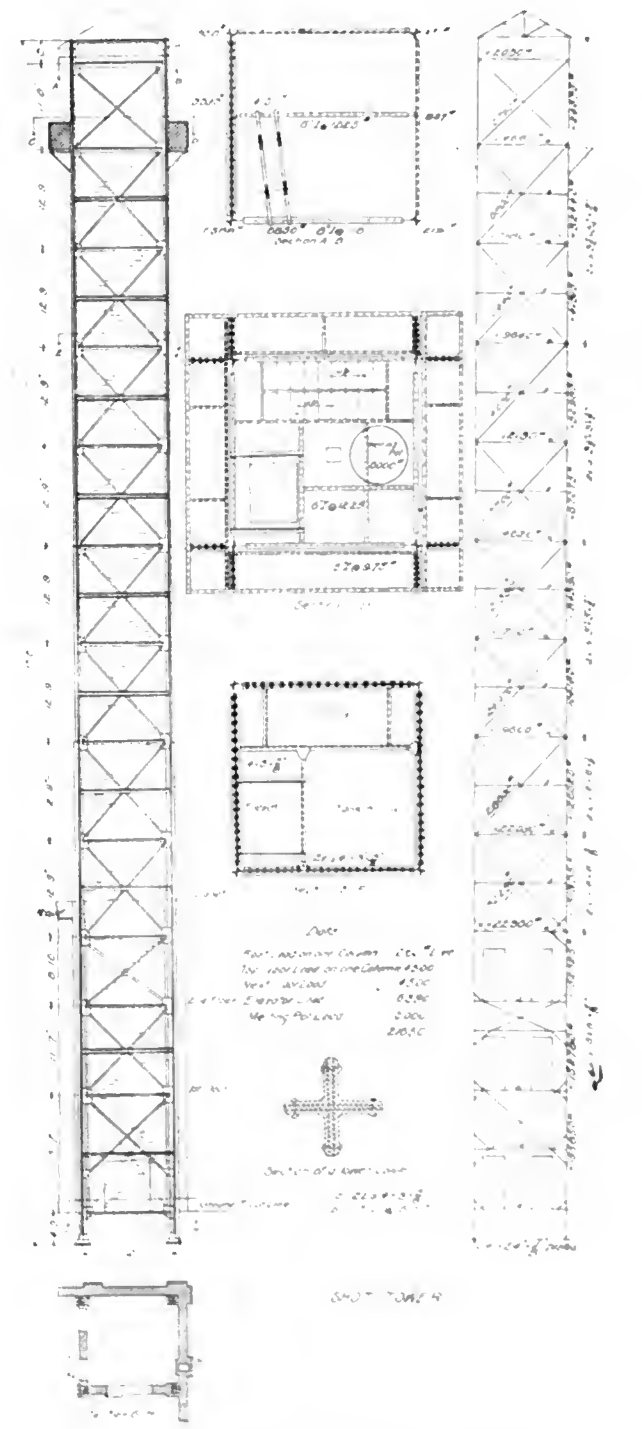
The Canada Metal Company, of Toronto, have let to the Ontario Wind Engine and Pump Company the contract for a shot tower to be built in connection with their new factory. The tower, which is still in the latter company's shops, will, when erected, be 160 ft. high, 12 ft. square, and be closed in with a corrugated iron sheathing. Erection will be commenced as soon as all the members are fabricated in the shops.

In designing the tower special attention had to be paid to bracing for wind loads—a factor very seldom considered in large flat buildings. This is necessary, not so much from any excess of weight, but from the excessive height of the tower relative to the width of the base. In fact, in designing the tower the wind load was the determining factor in the size of the members.

On account of the limited foundation space, the tower was built 12 ft. square and was kept uniform throughout, rather than using a larger base with a design tapering towards the top. This necessitated using heavier members, especially in the bottom panels, to get the same strength. The tower is built in an exterior corner of the factory, and is accessible from the different floors of the factory. This fact eliminated any bracing in the lower panels on that side as high as the factory roof. To overcome any danger from failure, the columns were built heavy enough to ensure a large factor of safety. To meet these several conditions the column members, as high as the factory roof, were each built of four 6 in. by 6 in. by ⅝ in. angles plated together, star connection, see figure. Beyond this two angles riveted back to back were used.

To meet the heavy overturning effect, the foundation for the shot tower, which was built simultaneously with the factory foundation, was made fairly massive, and to distribute the load under each pedestal over as large an area as possible, was built of concrete iron grillage. The foundation walls are 12 ft. square, 3½ ft. thick, and nearly 20 ft. deep. Eight 2-in. bolts were embedded in the concrete to firmly secure the tower. The total estimated weight of the tower is about 90,000 pounds.

On the top floor (see section C-D) is placed the melting pot and screens, with sufficient floor space for workmen, and around the tower is built a three-foot balcony. Material is elevated by means of an elevator, approximately 3 ft. by 4 ft., operated by machinery placed just to the north of the shot tower. A pair of stairs also leads to the top floor. Shot metal, on being elevated to the top floor by the elevator, is melted and poured through screens of the proper mesh, according to the size of shot required, and caught in a tank of water at the bottom. The liquid streams, in dropping through space, form into spherical globules, and are hardened when they hit the water.



Plans and sections for Shot Tower, showing wind loads in the different members

Creosoted Wood Block Pavements

Preparation of Blocks — Methods of Laying — Maximum Grades—First Cost and Maintenance

By Andrew F. Macallum, C. E.*

For a number of years untreated wood block pavements were laid in this country and the States and after repeated failures attention was directed to the use of preservatives. The first experiments made simply placed thoroughly dried blocks in a bath of creosote heated to a temperature of about 210 degrees F. until three pounds per cubic foot of creosote had been absorbed. While these pavements were fairly successful it was soon realized that the best results could not be secured by merely dipping the blocks and they were then treated with creosote under pressure until they absorbed from ten to twelve pounds of oil per cubic foot. Such a pavement laid in Indianapolis in 1898 gave such good results that city engineers began to appreciate the possibilities of treated wooden blocks and better results were obtained.

A small piece of wood block, treated with the creo-resinate process composed of one half creosote oil and one half resin, was laid on the west side of Yonge Street, Toronto, at Front street opposite the head office of the Bank of Montreal in 1896 and was still in good condition when taken up for a new pavement about two years ago. In the City of Hamilton probably more treated wood block pavements have been laid than in any other city in Canada and the first pavements put down in 1909 are as good yet as when laid, and although subjected to the heaviest kind of traffic have not to date cost a cent for maintenance. It has also been laid on residential streets where the residents assume its greater cost to asphalt for the added comfort through its quietness under traffic.

Types of Wood Used

The wood principally used has been Long Leaf (yellow) Southern pine which from experience has been found to give excellent results. Most specifications, now, however, admit Norway pine and tamarac as a result of experiments made on pavements laid in Minneapolis, which showed the suitability of these woods. No doubt other species of wood make satisfactory pavements but on account of the incomplete knowledge of their value as paving blocks city engineers as a rule prefer a wood that has been proven satisfactory. Blocks are generally from three to four inches wide and vary in depth from three to four and one-half inches and in length from 5 to 10 inches. The depth of blocks should not vary more than one sixteenth of an inch for a given size. As for all timber specifications the blocks should be sound, free from large or loose knots, shakes, worm holes and other similar defects. The annual rings are usually specified to average not less than six to the inch and the blocks to average 80 per cent. of heart wood or one block not to have less than 50 per cent. heart wood. The preservative used is usually a pure coal tar product free from petroleum oil or its products having a specific gravity of 1.10. Water gas tars have not proven satisfactory and should not be used.

With a view of obtaining opinions as to the most satisfactory amount of treatment required per cubic foot of block according to the experience of each city the writer has ascertained from replies from twenty cities in the United States that six of these cities use 16 pounds, two of them 18 pounds, and twelve of them 20 pounds depending to some extent on local conditions. The percentage of treatment will vary with the block as the denser and heavier the block the smaller is the quantity of oil which it absorbs. The sapwood will absorb a large percentage of the oil but if the block has not had the moisture first removed from the sapwood the oil will not be able to penetrate the block. Thus it is invariably found that a block which fails does so in the sapwood and the cause is an insufficient amount of oil or poor penetration of the sapwood.

* City Engineer, Hamilton, Ont. Before Good Roads Congress, Montreal.

Laying the Pavement

The base for wood block pavements should be of concrete from five to six inches deep, having the crown parallel to the required finished crown on the blocks. An uneven or irregular base is detrimental to any pavement as it is liable to cause a depression in the surface which the repeated impacts of waggon wheels is certain to increase, giving an uneven surface. Upon this concrete base is placed either a sand or mortar cushion, usually one inch deep with its surface struck by templates to a surface parallel to the contour of the finished pavement. Where sand is used it should be such that it will all pass through a quarter inch screen, besides being clean. When a mortar cushion is used, some engineers use a proportion of one of cement to three of clean sand to which sufficient water is added to insure the proper setting of the cement, while other engineers obtain good results by mixing and placing the cement and sand dry. This cushion is simply a means of securing a uniform surface for the blocks to rest upon and distribute the load. Alongside or between street car tracks, however, or on grades, sand cushions are apt to become uneven or flow due to the vibration of the rails or by water getting in alongside the rails, and washing the sand out, so that under these circumstances a concrete cushion should be used. Away from the car tracks the question of whether a sand or mortar cushion should be used is a matter of opinion. Sand gives a better cushioning effect and the blocks do not have to be rolled so soon after laying as when a mortar cushion is used, but the present tendency seems to favor a mortar cushion.

European practice does away with this cushion altogether, but the concrete base is finished off as smooth as a concrete sidewalk and to the exact contour of the surface of the pavement. This extra care and workmanship obtain results that are excellent in as much as the finished surface of the blocks have no depressions and consequently the wheels cause no impacts. In some cities it is not always possible to lay the blocks shortly after coming out of the treating plant, and the hot sun and wind, during shipment and the idle period before laying, is apt to check the blocks and cause the oil to exude. The blocks should be piled closely when delivered on the street and sprinkled or dipped in water before laying.

Expansion Joints

Generally the blocks are laid at right angles with the curbs with an expansion joint at each curb of from three quarters to an inch and a half according to the width of the pavement. Alongside the curbs three rows of block are laid parallel to the curbs with the expansion joint next to the curb. Placing a longitudinal row of blocks with an expansion joint on each side is sometimes done, but is not good practice as the single row of blocks between the joints will almost certainly rise up above the level of the adjoining pavement as the joints close up. Cross expansion joints have been used also by the writer when the treated blocks had been piled on a street for several months, but for fresh blocks properly treated they are not necessary on streets of heavy traffic. On streets of light traffic, however, there should be cross expansion joints placed from thirty to fifty feet apart and having a width of about three quarters of an inch. It is hardly necessary to say that the blocks should be laid with the grain vertical and having the joints in adjacent rows, broken by a lap of about 2 inches. The blocks should be laid neither too loose nor too tight, about one-eighth of an inch apart, so that a block can be raised without disturbing the surrounding blocks.

Roll the Surface

After the pavement is laid it should be rolled thoroughly with a roller varying from three to five tons until a perfect surface has been secured with no depressions and the blocks firmly in place. There should be no difficulty in this as the usual specification for blocks allows of a variation of but one sixteenth of an inch in depth so that if the foundation and cushion have been properly laid there is usually very little trouble about depth of the blocks. Alongside street railway tracks and about manholes special care should be taken in laying the blocks. It is usual in such cases to thicken the cushion so that the blocks shall be about one quarter of an inch above the wearing surface of the rail or cover and in a very short time the traffic will rub these blocks down to the level of the rail. Alongside rails, to prevent water flowing down and under the blocks, two methods are used: one is to place specially cut creosoted plank under the rail head to give a vertical surface against which the blocks are paved and the second and usual method is to plaster the web with a rich mixture of sand and cement to the width of the rail head and the blocks are then laid against this. As with other pavements it has been found that the girder lip rail is more satisfactory than the ordinary tee rail, unfortunately in use in most towns, for the permanence of the block on the inside or gauge side of the rail. Incidentally it may be said that no pavement will be satisfactory alongside a street railway track if the rails lack sufficient weight, stiffness and foundation to prevent movement especially at the joints.

Joint Filler

There is a diversity of opinion among engineers as to the best joint filler to be used. The American Society of Municipal Improvements recommend a suitable bituminous filler when the blocks are laid upon a sand cushion and a sand filler when laid on a mortar cushion. It is claimed for the bituminous filler, which fills the joints between the blocks about two-thirds their depth (the remaining depth being filled with sand) that it makes an absolutely waterproof pavement and that it eliminates all expansion difficulties as such block is surrounded with an individual expansion joint. Unless the filler is a suitable asphaltic cement with a high melting point and low penetration there is apt to be a sticky surplus left on the surface. This filler will cost about 15 cents per square yard more than a sand filler.

A cement grout filler has been used but unless the traffic can be kept off the pavement for at least ten days it is little better than a sand filler. The sand filler is generally used on streets of heavy traffic; the sand being coarse and sharp grained, and preferably heated before placing. The writer has used with excellent results a bituminous filler between, and one foot outside, of street railway tracks and a sand filler to the curb where three rows are again treated with a bituminous filler. From results obtained he does not consider the extra expense in using bituminous filler justified for such streets unless the traffic be very light. On bridge floors it is better practice to use a bituminous filler with the blocks. After the pavement is rolled sand to the depth of about a quarter of an inch is spread over the surface and the street is thrown open to traffic.

Maximum Grades

This method of construction is satisfactory up to a three per cent. grade, beyond which the blocks are laid in a different manner. The crown should be as light as possible, being just sufficient to shed the water freely, which applies also to the pavements between street railway tracks. When the grade of a proposed pavement exceeds three per cent. the question of a suitable pavement, and the method to be adopted in laying it, to meet the requirements of the traffic, becomes of interest. With the variability of conditions to be met with due to our climatic changes the limits of most paving material are soon reached, so far as the inclination of grade is concerned unless specially manufactured.

The writer inquired from twenty-four cities to ascertain the maximum grades upon which creosoted wood block had been laid and found that one city had laid this pavement on a seven per cent. grade, one on six per cent., three on five per cent., and five on three per cent. grades. The five to seven per cent. pavements were laid under two methods: The first method used was probably originated in the city of Hamilton and was used on upper James street where a block pavement was laid in 1909 on a five and a half per cent. grade. Each block had a strip one half inch in width and one half inch in depth cut off one face so that when the blocks were laid at right angles to the centre line of the street there was a space of a half inch between each row of blocks giving a good foothold for horses drawing traffic. These blocks were pitch filled and the cross grade of the street was sufficient to drain out any water. The same method was adopted on King Street west in the same city, during the same year, and I may say that both of these pavements have been very successful in meeting the conditions of heavy traffic on two of our main streets without a cent being spent for repairs or renewals since being laid.

Special Type of Blocks

The special cutting of the blocks in the manner described added considerably to the cost of the pavement and to obviate this the ordinary rectangular block was used with creosoted laths 5/8 in. x 2 in. laid between each cross row of blocks. This was pitch filled as in the first method and has been just as successful, being today in first class condition although subjected to fairly heavy traffic for four years.

On Ravenscliffe Avenue, Hamilton, a purely residential street, having a 6 per cent. grade, blocks spaced in this manner were laid. The reason for putting such a pavement on a street like this having very little traffic was that the residents insisted on a creosoted wooden-block pavement because of its quietness as compared with other pavements suitable for such a grade and it has fulfilled expectations.

Slipperiness

One of the criticisms made of treated wood block pavements is that it is slippery, but in the writer's experience he has found that there is very little difference between these blocks and sheet asphalt pavements. When covered with a light frost or snow, or when the weather is foggy and damp the pavement may become objectionably slippery. In traffic observations made at Philadelphia, Newark and other cities the evidence shown by the engineers at these places indicated that where treated wooden block and granite blocks were on parallel streets 70 per cent. of the teaming went on the wooden block. On Stuart street in the city of Hamilton the writer laid treated wooden blocks between the street car rails and granite block between the outside rails and curbs, the pavement being on a 5 per cent. grade. Although most of the traffic was of a heavy truck teaming nature it was found that fully 80 per cent. of the traffic except on wet days was on the wooden block.

First Cost and Maintenance

The first cost of wood block pavement is undoubtedly higher than that of most of the other paving materials; averaging in the City of Hamilton from $2.85 to $3.00 per square yard, exclusive of grading. When its cheapness of maintenance, ease of cleaning, low tractive resistance and durability are taken into consideration this pavement with its relatively high first cost will compare favorably and prove ultimately cheaper than one lower in first cost.

New Administration Building for Board of Education, College Street, Toronto

The fine new Administration Building, the new home of the Board of Education which is to be ready for occupation this year, is well ahead of its schedule. The Building is practically completed under the existing contracts which include the general construction, and the City has been asked to appropriate further for completion of the interior finish and fittings.

The building is situated on College Street, with the Main Facade directly opposite the University Group of Buildings, with a side entrance off a private driveway on the west.

The architecture is of a simple Classic Greek design. The feature of the main Facade is an Ionic Portico surmounted upon the heavy rusticated base

Fig. 1—Front Elevation, Administration Building, Toronto.

enclosing the principal floor. This Portico is flanked by two end pavilions, the whole supporting an attic storey.

Immediately under this Portico, the main entrance is situated which is a handsome modern adoption of the famous Erechtheion doorway. The spandrils between the stone columns are treated in Ornamental Cast Iron fitted with metal casements.

The building which is of fire proof construction is of skeleton steel frame, fireproofed with hollow tile and carried on concrete piles far below the surface of the ground, owing to the site being over the old Sleepy Hollow Creek. All floor and interior partitions are of hollow tile.

The material used throughout is a common grey stock brick with a recessed joint relieved with trimmings and Portico of Indiana limestone which makes a very successful combination.

The general treatment of the interior is very plain except the main entrance hall on the principal floor, the Members room and the Board room, which are treated to suit their respective importance.

The main hall has a simple plaster wall treatment relieved by ante-pilasters and supporting an entablature and deep panelling ceiling.

The axial line of the entrance leads to the handsome bronze enquiry wicket; adjacent to this is the elevator and staircase.

The enquiry wicket will be in touch with all parts of the building with an up-to-date telephone system.

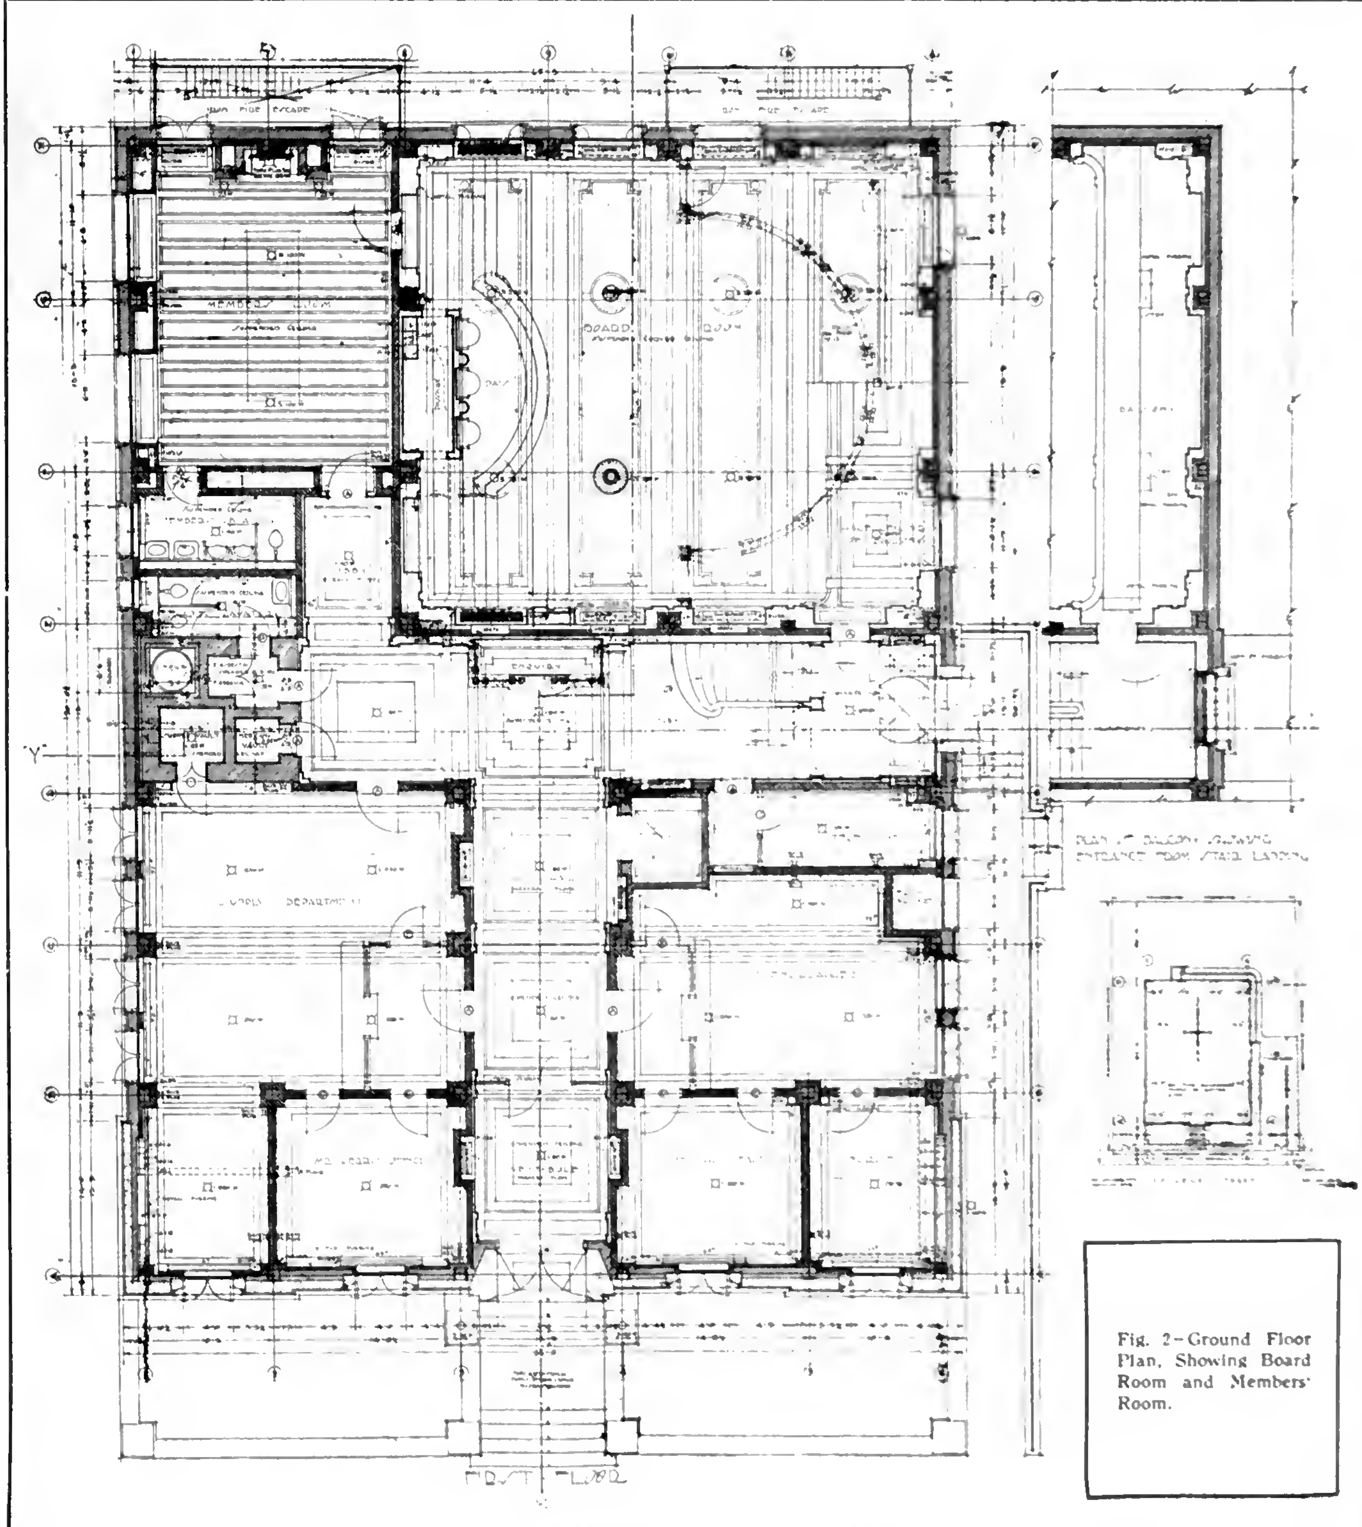


Fig. 2—Ground Floor Plan, Showing Board Room and Members' Room.

On the right and left of the entrance are situated the medical inspection and supply departments.

The members room is approached through an ornamental doorway on the left of the enquiry wicket. This room is designed as a comfortable meeting place for the members, being finished with panelling with stucco frieze over and a heavy beamed ceiling.

The lockers and telephone booths for the members are arranged in the wall panelling with special toilet accommodation directly off this room.

The special feature of this room is the large open brick fire place, over the shelf of which is a marble panel with bas relief carving symbolical of Education. The woodwork finish of the walls, ceiling and furniture will be of walnut.

A private entrance opens from the Members room into the Board room. The Board room is Italian Renaissance in design, the walls being treated with twin fluted pilasters of the Corinthian Order surmounted by an enriched Entablature with panelled frieze and supporting an ornamental segmental ceiling.

The focal point in this room is the Walnut Dais which is raised upon a platform. The desks and seats for the Members of the Board are arranged in horse shoe form, the space in the centre being occupied by tables for secretary and the press.

Ample provision for the public is arranged on the main floor and also in the gallery which is accessible from the main stair landings. These doorways are adjacent to the side entrance of the building.

The gallery is supported on the cantilever system so as not to obstruct the view with columns.

The general finish of the furniture and wood trim will be walnut.

The second floor is given up to two Committee rooms and the Secretary-Treasurer's Department, while the third floor is occupied by the Inspector's department, with ample accommodation for a private office for the Chief Inspector, and desk rooms and an

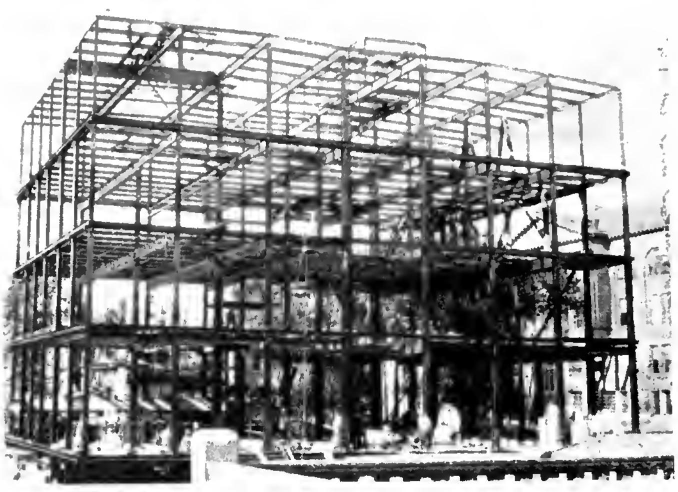

Fig. 3.—Steel Erection—Administration Building, Oct. 21, 1915

inspection room for the Junior Inspectors. The library is also here, and a room for supervising teachers. Use is also made of one room on this flat for a contractors' office in connection with the building department, which will wholly occupy the next floor, with suitable rooms for the various needs of the work. Special care has been given to the draughting room in providing ample light by installing skylights in addition to the windows.

The basement is given over to the heating and ventilating apparatus, fuel storage, caretaker's apartments, and kitchen and lunch rooms for the staff.

A special feature of the building is the fireproof vault, which is built on a separate foundation and is

Fig. 4.—Administration Building, Toronto. Erection Progress Jan. 6.

entirely independent from the skeleton construction of the building. Other notable aspects are the modern sanitary lavatories on the different floors, and the special ventilation system in the Board room, Members room and Committee rooms. Steam heating and fan ventilation are used throughout. An electric elevator will provide accommodation to all floors.

The building, which will cost about $140,000.00 inclusive of the interior finishings, was erected under the supervision of the department by the following constructors:—Masonry, H. N. Dancy & Son; Steel, Dom. Bridge Co.; Fireproof floors, J. A. Wickett, Ltd.; Roofing, W. E. Dillon Co. Ltd.; Carpenter, F. Armstrong; Painter, F. A. Ovens; Plasterer, A. D. Grant; Wiring, A. R. Rice & Co.; Plumbing & Heating, John Ritchie P. & H. Co. Ltd.; Iron work, Can. Orn. Iron Works; Heat control, Johnson Temp. Reg. Co.; Marble & Terrazzo, Can. Glass.

Metal for Shells

Specifications for Russian 3-inch shells call for a loading of 258 to 260 half-inch bullets, consisting of 4 parts lead and one of antimony. This requires practically 4.908 lb. lead and 1.217 lb. antimony per shell. In addition, fine stibnite mixed with magnesium powder is used to produce the smoke that enables an observer to register the point at which the shrapnel bursts. This calls for 0.0238 lb. stibnite and 0.02322 lb. magnesium per shell. British 3.3 inch shrapnel uses even more lead, the total weight of the bullets being 7.92 lb. and the composition 7 parts lead to one of antimony. This shell also requires 4.04 lb. copper and 1.87 lb. spelter.

The London Concrete Machinery Company have secured the contract from the Imperial Oil Company to supply two 21-cu. ft. batch mixers with gasoline power. Both mixers are to be used in the erection of the concrete work on the Imperial Oil Company's new plant at Pointe Aux Trembles, Que.

Methods and Costs of Garbage Disposal

Different Systems of Final Disposal Employed by U. S. Cities—Incineration and Reduction — By-Products — Methods of Financing Cost

(Concluded)

The following are some of the reports from cities which receive a revenue from by-products:

Minneapolis.—The steam generated lights and heats hospital and workhouse buildings, also lights 31 miles of streets. Estimated annual revenue, heat, $6,293.89; light, $1,080.62; street lights ($60 per arc), $4,657.48; total, $12,031.99.

Borough of Richmond.—West New Brighton incinerator uses clinker in manufacture of brick by mixing cement with ground clinker.

New Orleans.—Plans perfected to light streets and public buildings. Claimed that from 500 tons of garbage daily, 30,000,000 kw. can be generated a year.

Savannah.—Ninety-five per cent. of coal fuel previously used at pumping station is now saved by destructor. To operate waterworks pumping station it cost $81.90 per day. To operate the station and destructor it costs $46.50 per day, or a difference of $12,921 per year, this being 10 per cent. of the cost of the plant. This is expected to provide for repairs and amortization charges. Besides, the city has all of its refuse disposed of without cost at a central point and in a sanitary manner with freedom from nuisance. The clinker is used for road building and is estimated to have a value equal to the cost of hauling it from the plant.

All reports and experts agree that destructors are very successful from a sanitary standpoint and have the advantage over other methods in that the different classes of waste can be destroyed by one process and gathered in one collection. Several also agree that the destructors when properly constructed and operated, may be centrally located, thus reducing the cost of haul. Another point mentioned is that there is some revenue. The disadvantages pointed out by experts are that, if not properly designed and operated, there will be dust and odors, all refuse must be hauled to the plant and expert workmen must be employed.

The cost of operation varies from city to city, and in each city from month to month, depending upon the season of the year, composition of the garbage and climate. Most incinerator companies guarantee to operate their furnaces at full capacity at about 50 cents per ton. Milwaukee operates for about 57 cents per ton. The cost, including maintenance, depreciation and fixed charges, and operating expenses, averages from $1.50 to $2.50 and sometimes $3.00 per ton. The State Board of Health of Ohio found in its investigation that incineration cost from $1.97 to $2.50 in Canton, Ohio; $2.00 to $2.66 in Marion; $1.00 to $1.84 in Steubenville, and $2.58 in Zanesville, during a period of several years. These figures include interest, depreciation, maintenance and repair charges.

J. W. Turrentine, of the U. S. Department of Agriculture, who has just completed a study of garbage disposal plants, says in a recent bulletin that the average net cost of incineration per ton as obtained in a number of instances, is $2.11 per ton, and that in one of the cities considered there is a credit for power generated of 22 cents per ton of garbage incinerated.

Venable says, "the operating expenses are in the neighborhood of 50 cents per ton of kitchen garbage destroyed. The maintenance is from nothing to $1.00 per ton, according to the design and material employed, and the degree is from 10 per cent. to 50 per cent. per annum. In some furnaces a less cost of operation is claimed, but the claim of each builder should be subject to a careful investigation before being accepted as justifiable. The maintenance and depreciation charges are large in all crematories, but they depend to a great extent upon the character of the workmanship, and the quality of material used, as well as the designs. A poorly constructed crematory, even if of meritorious design, will not last a year, while a well constructed one of good design should last ten years or more with occasional replacement of worn parts."

Life of Plant

Most garbage incinerator manufacturers claim a life of twenty years for their plants with reasonable renewals.

Morse claims that when fuel is necessary the cost of destroying refuse and garbage in crematories is approximately 50 cents per ton. He also says that the cost of operating destructors is from 50 cents to 70 cents per ton for actual labor expenses, while the cost of operating the modern high-temperature destructor will not exceed from 50 cents to 60 cents per ton. Deducting credit for power, the cost will drop, he says, to 30 cents or less per ton. Depreciation and capital expenses are not included in Morse's calculations.

Greeley asserts that the cost of operation will range from about $1.00 to $1.50 per ton, "but local conditions may alter these limits."

C. O. Bartlett says: "So far as disposal of garbage is concerned, in incinerators, it is coming to be generally understood that this method is far from sanitary and is essentially wrong in that it neglects to obtain the value for the products so collected."

Rudolph Hering says: "In incineration, if sufficient fuel is added, the combustion can be made perfect and the garbage can be destroyed without offense and converted into unodorous gases, ashes and clinker. Whatever sanitary objection has been made to this process has resulted from preventable causes. Unless ashes and rubbish are combined with garbage in sufficient quantities to produce the necessary heat, the steam production is deficient and other fuel must be added."

Robert H. Wylde says of incineration at a high temperature: "Here we have a method that is at once sanitary, expeditious and economical in first cost and maintenance." He also points out that this method is free from nuisance, the plant may be centrally located, cost of collection minimized owing to the relative shortness of hauls, not necessary to maintain a separate collection, nor is there any necessity to keep refuse in separate cans.

W. F. Goodrich maintains that modern destructors are perfectly satisfactory and that there may be no fear of nuisance wherever they are located. He maintains that it should be the aim of officials to utilize the power produced for the best interests of the community.

William M. Venable says that cities of from 10,000 to 40,000 population should burn garbage and refuse, the problem to be solved being the advisability of attempting to utilize the heat generated by burning.

Reduction

When this method is used only garbage and dead animals can be destroyed, but when these kinds of wastes are broken down by means of heat, valuable by-products are recovered. This may be done in two ways, the processes being known as cooking and drying. In the first, garbage is cooked in large closed retorts by means of steam under pressure. It is then pressed, leaving grease and a dry cake known as tankage, which is used for fertilizer. In the drying method the grease is extracted by some volatile solvent like naphtha. The relative advantages of these two methods is disputed. At the present time the majority of plants are operated by the cooking method. C. O. Bartlett says that the cooking method does not permit of the recovery of any considerable portion of grease, but does provide for the retaining of most of the solids in dry form, after which they may be ground up to serve as a base for fertilizers. He also says it is open to some objection on account of escaping gases from the stack unless there are sufficient scrubbers.

Irwin S. Osborn sums up as follows the advantages and disadvantages of each process:

Drying Process

Advantages.—Cost of plant is less, due to equipment and building space required; the operating costs are less, due to amount of labor and power required.

Disadvantages.—Carbonizing of the grease in the dryer, due to high temperature required, so that the maximum amount of grease is not recovered; the material is not broken down so that solvent will act as readily on grease particles to allow maximum recovery; the mechanical condition of by-products is not as desirable without additional treatment; there is a greater volume of gases to be deodorized.

Cooking Process

Advantages.—The cells of the material are more completely broken down so that a larger amount of grease can be more readily recovered; all material is enclosed during the process so that the gases are more readily deodorized with less volume to be deodorized; in the modern plants the mechanical condition of the by-products is better.

Disadvantages.—Increased fixed cost of building and equipment; increased operating cost; increased maintenance cost.

He says that by-products produced by either have the same relative market value. In plants that have been operated by both methods, the experience has been that the additional amount of grease recovered by the cooking method has more than offset the increased costs and at the same time the odors were eliminated to a larger extent.

In establishing a reduction plant, Rudolph Herring says that the great fear is creating a nuisance. He further says that, owing to unpleasant odors apt to arise at the works, it is necessary to have good ventilation and also a subsequent treatment of some of the vapors and liquids which result from the process. These contingencies make it advisable, he believes, to locate the plant in a neighborhood where the possibility of occasional unpleasant odors will not materially injure value of adjoining property.

The Chicago Waste Commission contains this suggestion as a solution of the odor problem: "In addition to the steam and electrical power that can be furnished from a destructor plant to operate a reduction plant, the exhausting of all gases carrying odors from the reduction works and passing them through the destructor would prove one of the greatest advantages from a sanitary and economical standpoint to be derived from a combined method of disposal of all municipal wastes."

Osborn says: "Economical results may be obtained by utilization of heat in the disposal of garbage mixed with other refuse, by burning, but to prove satisfactory the maximum sanitary results must be obtained at a minimum cost, and when the quantity is such that it will warrant utilization the reduction method will continue to show more economical results, and with proper attention given to details and sanitary features the work can be conducted without nuisance."

Reduction is a method which can be adopted only by large cities. It seems to be usually agreed that cities with less than 100,000 population and producing less than 75 tons of garbage daily will find the reduction process will not pay as a business venture. One writer says in no place of less than 150,000 population can these kinds of plants be operated successfully. Venable places the minimum population at 100,000. He says that as approximately 80 per cent. to 90 per cent. of kitchen garbage is water and only 10 to 20 per cent. is composed of grease and other substances it takes a large amount of garbage to make a reduction plant profitable.

Parsons fixed the minimum population at 200,000. He points out in his book on "The Disposal of Municipal Refuse" the following advantages and disadvantages of the method:

Advantages.—The organic or putrescible matter of the garbage is extracted into compounds which are harmless,—grease and tankage; it thus saves those components which have a material intrinsic value; the garbage is cared for in a sanitary manner; the cost is about $1.80 to $2.00 per ton to the city and no revenue from the grease and tankage; as the works are situated some distance from the city the haulage is only on the garbage; when properly designed and carefully operated, the process need not be a nuisance, and its adoption adds a new manufacturing industry.

Disadvantages.—The first cost is high; expensive machinery and apparatus are required; the cost of renewals and repairs is large; the odors and smells are apt to be given off and the expense to prevent such an annoyance; the distant location of the plant from the city in order that odors may be least objectionable; being a manufacturing plant it should be erected and operated by private interests; being operated for profit there is danger that the works may become a nuisance; requiring skilled labor, there is some danger of strikes; the garbage must be separately collected; there will always be some foreign material, tin cans and the like, which must be sorted out at the works; there being but one plant the system would be crippled by fire or by any cause stopping the plant; the plant cannot be divided, as small plants do not pay; the process cares for the garbage only, leaving the remaining refuse to be otherwise treated.

Cost of Reduction

The cost of a reduction plant will range from $1,500 to $3,000 per ton of daily capacity, according to published reports.

The gross cost of garbage destruction by the reduction method varies from $1.50 to $2.50 per ton of raw garbage. In only a few instances does the sale of the by-products meet or exceed expenses. In a majority of cases, the process is carried on by private companies, the most being subsidized by cities to amounts varying from 50 cents to $2.50 per ton. A few companies pay the city for all garbage delivered to the plant.

The by-products of the reduction method are grease and tankage. It is generally agreed that ordinary garbage contains from 2 to 3 per cent. by weight of grease and must yield from 200 to 400 lbs. of tankage per ton.

J. W. Turrentine says that on the basis of figures obtained in the operation of a number of reduction plants, it is shown that the average cost of reduction is $2.41 per ton, and the gross receipts $3.30 per ton, giving a profit of 89 cents per ton raw garbage. He asserts that when consideration of cost of collection is excluded, the rendering of garbage is distinctly more profitable than incineration.

Cleveland and Columbus have been the cities most successful in operating reduction plants. In 1914 the Columbus plant received 21,628.97 tons of garbage, or 211 lbs. of garbage per capita. From this and the 183 large dead animals received, the actual production was as follows: Grease, 1,186,985 lbs.; tankage, 1,753 tons, hides, 183. The value of these by-products were: Grease, $52,672.21; tankage, $12,987.84; hides, $1,062.30, or a total of $66,772.35.

Each ton of garbage produced 54.87 lbs. of grease and 162.1 pounds of tankage. The grease value per ton of garbage was $2,435; the tankage, 60 cents, and the hides, 5 cents, or a total of $3.085 per ton of garbage. The actual cost of operation was $40,220.78, or $1.859 per ton. The net profits were $26,501.57, or $1.226 per ton of garbage.

Cleveland, in 1912, produced 2,940,000 lbs. of grease and 10,016,000 lbs. of tankage, the city receiving for them $151,162.48. This reduction cost per ton of green garbage was $1.97½, and the earnings per ton of green garbage was $3.47, making the net earnings per ton of garbage, $1.49½.

New York City sells its garbage to a private company. It made a contract for 1914 to 1916, inclusive, and the right to renew the contract for two more years on the same terms and conditions. The city receives at the rate of $62,500 for the first, $87,500 for the second, and $112,500 for the third and each of the succeeding two years.

The Practical Selection of Aggregates for Concrete Construction*

It is not the intention of this article to deal with the hardness, angularity, roughness, roundness, or general fitness of any given aggregate. The aggregates are supposed to be clean and of such quality that the work at hand can be performed by properly combining them to get the desired result. The article is also based on the assumption that the reader has an intimate knowledge of the proper degree of wetness or dryness necessary to attain the best results; also that the dangers of inefficient mixing and placing of concrete will at times cause disastrous results, no matter how good the materials.

Sand

It would not be amiss to state that the best sand (or stone) is that which has grains of all sizes present, such that the smaller grains fill the voids of the larger, the percentage of any particular size being only sufficient to fill the voids between the grains of the next larger. Sand is generally considered to be the finer aggregate, having grains ¼-in. diameter or less. Moist sand occupies more space and has more voids than dry or saturated sand, this difference ranges from 5 per cent. to 10 per cent., and is entirely dependent on amount of moisture. The maximum size of sand grains can only be determined by the size and graduation of the large aggregate. The larger the aggregate, the larger the sand (the coarser sand). When we combine small gravel or stone 1 in., ¾ in. or less, with coarse sand ¼ in. to 1-20 in., we get concrete, "that's all." When we combine 1 in., ¾ in., etc., aggregate with fine sand graded through all sizes (⅛ in. max. size) down to the finest, we get maximum strength and maximum density. The smaller the coarse aggregate the smaller the sand grain.

The best sand for 2½-in. stone varies from 1/3 to 0.-3 meshes per lin. inch.

The best sand for 1½-in. stone varies from 1/5 in. to 0.-5 meshes per lin. inch.

The best sand for 1-in. stone varies from 1/6 in. to 0.-6 meshes per lin. inch.

The best sand for ¾-in. stone varies from 1/10 in. to 0.-10 meshes per lin. inch.

The best sand for ½-in. stone varies from 1/14 in. to 0.-14 meshes per lin. inch.

This can readily be established by trial. These sand sizes mixed with graded stone of above-mentioned sizes will give least volume, maximum density, greatest weight per cubic foot. After you have once established this fact, use all the cement necessary to attain the required strength. Sand cement tensile tests are not a true index to the compressive strength of concrete, unless we grade the sand to the size necessary to give maximum density for the coarse aggregate to be used.

Large Aggregate

Now take up the large aggregate, which we will consider as gravel. The same distinguishing line will have to be drawn as to what constitutes gravel.

2-in. to 1/4-in. graded gravel has an average of 33 per cent. voids.

1½-in. to 1/5-in. graded gravel has an average of 35 per cent. voids.

1-in. to 1/6-in. graded gravel has an average of 37 per cent. voids.

¾-in. to 1/10-in. graded gravel has an average of 40 per cent. voids.

½-in. to 1/14-in. graded gravel has an average of 45 per cent. voids.

You cannot combine small gravel 1 in. or less with sand, no matter how you grade it and get so few voids, so heavy a mixture, so dense a mass, as when you use the larger size gravel. The reason for this is you cannot get the proper graduation of sizes, and on account

* By R. J. Borhek in Engineering & Contracting.

of the displacement of the finer particles due to the large sizes of gravel. For maximum density your proportion would be for the different sized stone, considering sand 1/4 in. and under—

2-in. stone graded to 1/4-in., 33 per cent. sand.
1 1/2-in. stone graded to 1/4-in., 38 per cent. sand.
1-in. stone graded to 1/4-in., 47 per cent. sand.
3/4-in. stone graded to 1/4-in., 54 per cent. sand.
1/2-in. stone graded to 1/4-in., 66 per cent. sand.

Use of Coarse Sand

One very common failing is when small gravel or stone is used the sand is too coarse or else not enough of it is used. The voidage in fine gravel or stone, even though the grading be scientifically correct, cannot possibly be as low as when a large graded aggregate is used.

The reason for the denser and harder concrete is this: The coarse particles having a larger volume displace a large proportion of the fine, thus affording an excess of mortar.

We might illustrate this by comparing the volumes and surface areas of particles of different sizes and diameter. The argument will at once be brought forth that the gravel particles are not perfect spheres. That is true enough, but consider also that a 2-in. diameter sphere is equal in volume to two ellipsoids having a 2-in. long axis by 1-in. short axis. Choose any other figures approximately the shape of a particle of gravel, spherical sector, segment or zone, measure up the actual surface area by forming a plastic mould around same, planimeter the area and you will conclude that the average gravel particle passing through a given screen approximates a sphere in volume and surface area. Now, with this assumption proceed as follows:
